SI

Trust Game Setting. Overview. In general, a trust game begins with an investor receiving an initial endowment of experimental currency. The game then proceeds through two sequential stages of play. In the first stage, each investor decides how much of the initial endowment to keep and how much to "invest" with a paired (i.e., within-dyad) trustee. Whatever amount the investor sends is tripled in value before the trustee receives it. In the game's second stage, the trustee decides how much of the amount received to "return" to the investor. No communication is allowed, other than the notification of each subject's decision to the other subject. Subject anonymity is maintained throughout. Gains from trade result from the tripling of the investment. Thus, a dyad's gains from trade are maximized when the investor invests the entire endowment.

The anonymous one-shot single-dyad trust game has been conducted with diverse subject pools around the world (1, 2). In sharp contrast to neoclassical economic predictions, investors frequently invest money with trustees, and trustees frequently reciprocate by sharing the gains from trade with investors.

Multiperiod Trust Game. Recently, King-Casas et al. use a repeated single-dyad version of the trust game to study the evolution of reputation and trust in two-person economic exchange (3). King-Casas et al. argued that repeated transactions are closer to real-life social interactions than a one-shot game, and the game structure allows for (i) development of bidirectional trust, in that both investor and trustee assume risk that investments may not be reciprocated in future interactions, and (ii) reputation formation as both subjects developmental models of one another through their repeated exchange.

Regression analyses in King-Casas *et al.* show that reciprocity (fractional change in amount sent by one subject in response to fractional change in amount sent by the other) significantly predicts trust (amount sent by a subject). In addition, amounts sent in the current period are positively correlated with the level and change in amounts received most recently. Furthermore, as revealed by fMRI neural imaging, trustees begin to anticipate investors' decisions and develop an "intention to trust" even before they receive investments. Notably, reputation formation occurs even though subjects cannot keep external records, and subjects appear to keep track of at least the last two amounts sent and received. We adopt the 10 period, single-dyad game as our no recordkeeping single-dyad exchange setting, and use this as a baseline condition to investigate the effects of economic complexity and recordkeeping availability.

Multiperiod, Multi-dyad Trust Game. To increase exchange complexity in a natural manner, we extend the repeated game to allow each subject to simultaneously participate in five dyads, retaining the same role (investor or trustee) and matched partners through all 10 periods. Subjects are notified only of the decisions that affect themselves. For example, trustee B1 learns how much investor A1 chose to send to him, but not how much investor A1 sent to the other trustees (i.e., B2 through B5). Although the multiple dyads allow each subject to try out several strategies, it also means that they have to identify different partners' strategies simultaneously and develop appropriate responses. In addition, the multi-dyad exchange setting allows for spillover and feedback effects across subjects that are not possible in the single-dyad exchange setting.

**Procedures.** Each condition-specific experiment-session included 10 subjects, each of whom was randomly assigned to be either an

investor or a trustee (with the restriction that each session contains 5 investors and 5 trustees). Further, each experiment-session included 10 trading periods. Subjects were not informed of the number of periods to mitigate end game effects, although they were informed via recruiting materials that the experiment would last  $\approx 2$  h. No experiment-session lasted longer than 90 min.

Subjects received and read written experiment instructions. Subjects then took a quiz to ensure sufficient understanding of experiment instructions. The experiment facilitator checked quiz answers and resolved discrepancies privately before the beginning of the first period. The facilitator collected all instructions and quizzes and ensured subjects had no other materials or writing instruments available. A condition-specific, short-form version of experiment instructions was taped to the wall next to the computer monitor for reference.

Each trading period began with investors deciding how much of 10 units of experiment currency (i.e., *lira*) to invest in the paired trustee(s). In the multi-dyad conditions, investors had 5 separate endowments of 10 *lira* for each of the 5 trustees with whom the investor was paired. All investors' investment decisions were required before trustees received investment information. Similarly, all trustees' "return" decisions were required before both player types received feedback information. Investors received feedback information in the form of what each paired-trustee sent. Trustees received feedback information in the form of what was received from each paired-investor (i.e., the tripled investment amount). The next trading period began once all subjects confirmed they were finished reviewing feedback.

At the end of the tenth trading period, subjects completed a short questionnaire containing strategy-oriented and demographic questions. The *lira* learned for all periods was summed and converted to cash at a rate that varies by experimental condition to equalize the maximum possible payout per subject across exchange conditions (0.04 per *lira* in the multi-dyad condition and 0.20 per *lira* in the single-dyad condition). Because each subject in the multi-dyad setting participates in 5 dyads each period, we set the conversion rate in the multi-dyad setting at 1/5 that of the single-dyad setting.

**Computer Software and Data Collection.** Subjects in a laboratory setting interacted anonymously over a local computer network facilitated by *z-Tree* (Zurich Toolbox for Readymade Economic Experiments) software (4). The program kept track of all amounts sent and received by each subject in each period and provided designated feedback information. The software also tracked the time at which each subject confirmed investment or return decisions in each period.

In recordkeeping conditions, we provided a text-based electronic notebook to subjects. The notebook is a blank textbox, situated at the right side of the computer screen. The *Textbox* program recorded the contents of the textbox every 5 s for the length of the experiment-session, providing data regarding the timing, content, and extent of recordkeeping engaged in by individual subjects. This program is the only method of personal external recordkeeping available to subjects. Subjects did not have access to paper and pencils, nor could they use computer programs other than *z-Tree* and *Textbox* (the latter available for only those subjects in the recordkeeping condition).

**Experiment Instructions.** The SI Appendix contains the written instructions received by all subjects in the multi-dyad record-

keeping and the single-dyad recordkeeping conditions. Experiment instructions for the no recordkeeping conditions differed only via the lack of notational and pictorial reference to the on-screen textbox. Subject roles were referred to as "A-players" (investors) and "B-players" (trustees) to avoid implications associated with role-descriptions used in the paper.

Description of Subject Demographics, Statistical Tests, and Results. Subject Demographics. We conducted our experiments at the Center for Interuniversity Research and Analysis on Organization (CIRANO) in Montreal, Canada. CIRANO staff recruited subjects and ran 20 sessions (5 sessions for each experimental condition) during November and December 2005. Two hundred subjects (115 males and 85 females) were recruited by CIRANO from a standard subject pool and remain anonymous to the authors. Demographic data (e.g., subject age, sex, etc.) were collected in a computerized postexperimental questionnaire. The average age of the subjects was 25.5 years and 78% (39%) were 26 years of age or older. One hundred fifteen subjects were graduate students, 82 were undergraduates, and 3 were nonstudents. One hundred sixty-four subjects had been subjects in a prior experiment at CIRANO. The postexperimental questionnaire also elicited qualitative descriptions of subjects' strategies in making decisions during the experiment.

Statistical Tests. We evaluated differences in performance between the 5 economies with recordkeeping and 5 economies without recordkeeping. For a particular performance index (such as average return in an economy) we ranked the 10 economies and determined at what significance level the null hypotheses of no difference in the ranks was rejected. Mann and Whitney (5) provide the calculation of the exact distribution of ranks under a hypothesis of no difference.

Differences Between Multi-Dyad and Single-Dyad Economies. More subjects made marks on their computer screens in the multi-dyad condition than in the single-dyad condition when recordkeeping was available and this tendency was more pronounced for investors than for trustees (Table S1). Seventy-eight percent of all subjects made marks in the multi-dyad condition compared with 50% in the single-dyad condition. For investors, 88% (48%) made marks in the multi- (single-) dyad condition. Thirty-six subjects initiated typing in the first period of play; 27 of these subjects were in the multi-dyad condition and 9 were in the single-dyad condition (Table S1).

We also measured subjects' time to decision (see Table S2). Consistent with our expectations, the mean and median times to decision indicate that both investors and trustees took longer to make decisions in the multi-dyad condition than in the single-dyad condition. In general, trustees took longer to make decisions than investors and subjects in the single-dyad condition showed larger percentage declines in decision times than subjects in the multi-dyad condition. These data are consistent with greater cognitive demands in the multi-dyad condition that manifest themselves in actual use of recordkeeping and longer decision times.

The content of records depends on the complexity of the exchange condition (Table S3). Across both economy types, the majority of subjects who kept records included numbers in their records (92% in the multi-dyad condition and 100% in the single-dyad condition). Records in the single-dyad condition were more likely (than those in the multi-dyad condition) to contain qualitative descriptions of past behavior (e.g., "He returns more than I send"), whereas those in the multi-dyad condition were more likely to include some form of judgment (e.g., "2 and 4 are cheap").

As shown in Fig. S1, the cumulative character count is higher in the multi-dyad condition than in the single-dyad condition. Further, the cumulative character count rose steadily across the

10 periods, regardless of the exchange condition, indicating that recordkeeping was maintained throughout the sessions.

The percentage of maximum investments in the multi-dyad recordkeeping condition exceeded that in the other three conditions in both subperiods (Table S4). The percentage of zero investments was higher in later periods than in earlier periods (Table S4). This finding is consistent with investors excluding trustees after a history of behavior existed. In the multi-dyad condition, the increase in the percentage of zero investments across the subperiods was higher when recordkeeping was possible than when it was not. This pattern was not observed in the single-dyad condition.

The percentage of cases where the trustee split evenly the amount received from the investor (Table S5) or the percentage where the trustee evenly divided the total pie (Table S5) was higher in later periods for all four conditions. In the multi-dyad condition, this effect was most pronounced when recordkeeping was possible, in large part because the number of zero investments increased to a far greater extent. This tendency was not present in the single-dyad exchange condition as the number of positive investments was similar across the subperiods.

Total payouts were highest in the multi-dyad recordkeeping economies and were lowest in the multi-dyad economies without recordkeeping (Table S6). Investors earned a relatively higher mean and median total payout and thus a higher percentage of total earnings than trustees in all conditions (Table S6). In addition, the most equal division of total payouts occurred in the multi-dyad exchange condition with recordkeeping.

**Calculation of Image Scores.** Table S7 describes the calculation of investor and trustee image scores used in our analyses.

**Underlying Data Used to Produce Figures in the Main Paper.** The estimates used to produce Figs. 1–4 in the main text are shown in Table S8.

Additional Analyses. In the main paper, we show that recordkeeping is associated with beneficial risk reduction. Our main analysis focuses on investor risk, because as the first mover the investor incurs greater risk. Here, we provide supplemental analyses related to trustee risk.

The risk to a trustee in the trust game arises because an investor may be unwilling to invest large amounts—that is, a trustee earns a positive payoff only when the investment is positive. The results in the main paper suggest that investors discriminate against nonreciprocating trustees in a recordkeeping economy. But, do trustees face greater risk that investors will make overall lower investments in a recordkeeping economy or, even if recordkeeping investors make large investments, are trustees overall disadvantaged in terms of their overall income?

Our evidence suggests these concerns are without merit for our sample. First, there is no evidence to suggest that investors in the recordkeeping economies make lower average investments. On average, investors in the 5 recordkeeping economies invested 56.5% of the maximum amount possible compared with 49.9% in the 5 no recordkeeping economies (Table S6). The difference in mean investment percentage between recordkeeping and no recordkeeping economies is not statistically distinguishable from zero at  $P \leq 0.10$ .

Total economy-wide investment was also less variable across the 5 recordkeeping economies than the 5 no recordkeeping economies. Our measure of cross-economy investment variability is the coefficient of variation of total economy-wide investment for a given period. The coefficient of variation in economy-wide investment is lower for the recordkeeping economies in both subperiods (Table S9). The mean coefficient of variation (across periods) in total economy-wide investment as a percentage of the maximum possible was 0.269 for the recordkeeping economies and 0.288 for the no recordkeeping economies in periods 1–5. This measure declined for the recordkeeping economies in periods 6–10, but increased for the no recordkeeping

economies. Finally, trustees earned an average income of \$19.05 in the recordkeeping economies compared with \$18.25 in the no recordkeeping economies (Table S6).

Tables \$10 and \$11 contain additional analyses that accompany those reported in the main paper. Table \$10 presents analyses related to subjects' image scores and data and related tests for the image scores of subjects in single-dyad economies. These tests are analogous to those presented for the multi-dyad economies (Figs. 1 and 2 and Table \$8. Table \$10 also includes similar data and tests related to multi-dyad (single-dyad) economies. However, these data are based on a continuous image score; specifically, investors' image scores are based on the dyad-specific investment amount whereas trustees' image scores are based on dyad-specific return on endowment. Table \$11 presents analyses related to correlations between trading partners' behavior in single-dyad economies and are are analogous to those presented for the multi-dyad economies (Table 1 and Table \$8).

Please note that in a single-dyad session, 10 subjects were used but each individual investor was allowed to transact only with a single trustee, and vice versa. Thus, we have computed a correlation coefficient for each session. (Note that an individual correlation is not calculable for a single person in a given period because n = 1.) However, the resultant statistic is not subject to straightforward interpretation. For example, a positive correlation between period t investments and period t-1 trustee image scores in a multi-dyad session arises because each individual investor is making relative comparisons between the various trustees. In this sense, the image score captures differences between trustees that lead to differences in investments decisions. In contrast, because a single-dyad session pairs each investor with a single trustee, the investor makes no relative comparison between trustees. Thus, any cross-correlation that is estimated from the session data for the single-dyad economies is not directly comparable to that obtained from the multi-dyad economies.

## Table S7. Calculation of investor and trustee image scores

Trustee image score changes for a given period

+2 points for large positive returns

Large positive returns are defined as an amount sent back by the trustee that is ≥1/2 the amount received by the trustee (three times the investment)

+1 point for small positive returns

Small positive returns are defined as an amount sent back by the trustee that exceeds the investor's investment but is less than one-half the amount received by the trustee (three times the investment)

No change (i.e., 0 points) when no trustee decision is made

0 points when the trustee has received nothing from the investor and no decision by the trustee is required

-1 point for small negative returns

Small negative returns are defined as an amount sent back by the trustee that is ≥1/2 of the investor's investment, but is less than the amount invested

-2 points for large negative returns

Large negative returns are defined as an amount sent back by the trustee that is <1/2 of the investor's investment Investor image score changes for a given period

+2 points for very large investments

Very large investments are those equal to 9 or 10 lira

+1 point for large investments

Large investments are those between 6 and 8 lira

0 points for modest investments

Modest investments are those equal to 5 lira

-1 point for small investments

Small investments are those between 2 and 4 lira

-2 points for very small investments

Very small investments are those equal to 0 or 1 lira

Null values represent undefined correlations given zero variance for one or more subjects. These values are not included in means or related tests. These limited occurrences are found in single-dyad economies.

Includes statistical test results not included elsewhere.

Table S11. Additional Analyses - Single-Dyad Economies Correlations
