Homology Search and Phylogenetic Study

Given a query amino acid sequence, find similar sequences with a common evolutionary history.

Procedure:

STEP 1: Retrieve the query sequence (by ID) from databases (getAminoAcidSequenceUMA service):

STEP 2: Perform a homology search (Blast service)

STEP 3: Select the more similar sequences from the Blast report (getBestHitsFromBlast & getAminoAcidSequenceCollection)

STEP 4: Perform a Multiple Sequence Alignment (Clustalw service)

STEP 5: Built-up a Phylogenetic Tree (CreateTreeFromClustalw service)

Start the exercise by contact the MOWServ client at <u>www.inab.org/MOWServ</u> or use any of the available mirrors (e.g. <u>http://www.chirimoyo.ac.uma.es/MOWServ</u>)

MOWServ's main screen. The upper panel allows authenticated sessions to be established, providing user files system space. On the left, the browsing frame for service, datatype and namespaces identification (including text based searches, etc). The main panel is used for requesting service parameter, to display results, etc.

The exercise has been tested using the MOWServ client at the University of Malaga (UMA), and using the services provided by UMA authority at <u>http://www.chirimoyo.ac.uma.es/MOWServ</u> (in most cases, services have identified with the suffix UMA to facilitate the exercise reproduction)

STEP 1: Amino Acid Sequence retrieval.

The first step will retrieve the protein sequence from its identifier.

Browse the service tree (left panel): Services -> Service -> Bioinformatics -> Database -> Retrieving -> Getting sequences -> Getting AminoAcids

An alternative way is to use the search box (left panel) to filter services by keyword, or the Discovering engine (Magallanes) in the right hand side tab.

(Observe that several services with similar or even with the same name can be available, corresponding to services supplied by different authorities).

Click in the **getAminoAcidSequenceUMA** service to open the parameter interface. In this interface, there are two main groups of parameters (see Figure):

INPUT PARAMETERS: ID specification (use SMN_HUMAN as example).

OUTPUT NAME for the file that will contain the retrieved sequence. The system provides a by default name that can be modified by the user (default name; service name + Date + GM time). In this exercise we rename the output file to: "SMN_HUMAN Object"

Once the submit button is clicked, the progress of the service can be monitored in "User tasks" tab using reload in case of the service require more than few seconds, and when the process had finished, the result can be displayed in different formats also from this tab:

			Stats		
		Finished	Total		
		1	1		
		Item 1 - 1 of 1			
ID	Service			State	
2	2698	getAminoAcid	SequenceUMA		Finished
Nai	me	Туре		View	
SM	N_HUMAN Object	AminoAcidSeq	uence	an a	

• XML: View the object in XML format like a BioMOBY object (click on the below icons to view how your output objects are shown).

- HTML: View the object in a user-friendly window with HTML format. The different objects have different viewers (click on the below icons to view how your output objects are shown).
- Download: Download the object to your local computer.

If you click on an object name, a list of services accepting this object will appear, thus making it easier to perform additional analysis on the results.

STEP 2: Homology Search.

To carry-out this task the NCBIblastp service can be used (write this text in the search box and use the "expand all" button to display the highlighted selections. Click on the chosen service (let's use the runNCBIBlastp1 service provided by UMA) and select the Input file Name (SMN_HUMAN Object). By default the only object we have created appear as input, so we only need to click submit to run.

Main	User Objects	User Tasks	Workflows	Discovering

STEP 3: Select the most similar sequences from Blast report

This step is aimed to produce a file with a set (Collection) of the most similar sequences from the Blast report.

This is solved in two sub-steps: (a) select the IDs of the most similar sequences using a threshold based on the Blast E-value; and (b) use the IDs to retrieve the sequences and store in a collection file.

For the selection of the most similar sequences we will execute the service getBestHitsFromBlast (Services -> Service -> ObjectHandling -> Parsing) using 0,02 and 5 as Threshold value and number of best hits to be retrieved (default parameters).

		Home Service Tutorial

When we have the ID list we will need to retrieve the corresponding sequences from databases. In this way we will use getAminoAcidSequenceCollection service (Services -> Service -> Database -> Retrieving -> GettingSequences -> GettingAminoacids) in order to retrieve the aminoacid sequences from the previous IDs/databases (object collection) to produce an amino acid sequence collection. When the service has finished we can look at the created objects in the html viewer. The output file can be renamed as "AA Collection SMN_HUMAN" to distinguish from the rest of objects.

STEP 4: Multiple Alignment.

Now we will run the ClustalW program with the most similar found sequences to our query sequence to build up a multiple alignment with them.

The used service in this step is runClustalwFastUMA, located on the tree branch: Service -> Service -> Bioinformatics -> Alignment -> Multiple_Sequence_Comparison. This service has several input parameters that we will leave in its default values (it can be changed in order to modify the final alignment). The service has also an input where we select the previous sequence collection.

Now we can choose an output name (e.g. Clustalw SMN_HUMAN) and submit the task.

STEP 5: Phylogenetic Tree

Finally we will build a phylogenetic tree in phylip format which can be visualized with a specific viewer.

To construct the phylogenetic tree from the clustalw output, we will run the runCreateTreeFromClustalw service (Services -> Service -> Bioinformatics -> Distances -> Phylogenetics -> Phylogenetics_Tree_Computing). This service has an only input parameter:

Clustalw_output: We will select the before clustalw_report from the object list in the interface (Clustalw SMN_HUMAN).

Again we have to include an output name and submit the task.

Main	User Objects	User Tasks	Workflows	Discovering					
	[www.bioinfo.	uma.es] runC	reateTreeFro	nClustalw: Pr	oduces a phylogenetic tre	e with dnd format f	from a ClustalW multiple	alignment	
					INPUT PARAMETERS				
	NAME		TYPE	VALUE					
	Clustalw_output	Clus	talw_Text	Clustalw	SMN_HUMAN	•	Create	Upload	
					OUTPUT NAME				
	TYPE		NAME			-			
	Newick_Text								
		Submit		http://chirimoyo.ac	.uma.es/cgi-bin/services/MobyEd_	dispatcher.cgi 💌	Reset		
				Home	Service Tutori	əl			

Now, when the service finishes, we can see the created object, as a phylogenetic tree, with the html viewer. Here, the initial query sequence (SMN_HUMAN or Q16637; Survival motor neuron protein) is mostly linked with the other proteins from the same family (O02771, O18870, rat and mouse homologues, O35876, and P97801, and one fish protein Q16637.

In short, with this set of services we have obtained the SMN_HUMAN homologues from Swiss-Prot database and their phylogenetic relations, but also have the relations with other distant proteins sharing domains with our query sequence.

Additionally we could have executed other intermediated services, if they are considered useful for our analysis.
