

Comprehensive analysis of the palindromic motif TCTCGCGAGA, a regulatory element of the *HNRNPK* promoter

Michał Mikula, Paweł Gaj, Karolina Dzwonek, Tymon Rubel, Jakub Karczmarski, Agnieszka Paziewska, Artur Dzwonek, Piotr Bragoszewski,
Michał Dadlez, Jerzy Ostrowski

SUPPLEMENTARY DATA

Supplementary method 1

The maximum mass deviation (MMD) for precursor and fragment ions were established in a procedure involving two database searches separated by a mass recalibration step. Data from each LC-MS/MS run was searched in a first pass with permissive MMD settings (± 40 ppm for precursor ions and ± 0.8 Da for fragment ions). The resulting Mascot DAT files were next imported to an in-house Java tool (DATViewer, <http://www.ire.pw.edu.pl/~trubel/soft/ms/mascotscan>) which implements a procedure for systematic mass errors elimination and high accuracy MMD estimation. Only PSMs with a score value exceeding the smaller of the Mascot identity and homology thresholds were used for the mass accuracy assessment. For each LC-MS/MS run the mass correction was performed by fitting a smooth LOESS curve to the scatterplot of the observed mass errors versus precursor ions masses. The obtained normalization function was then used for the entire set of precursor ions. A separate calibration function was also calculated for fragmentation spectra on the basis of the masses of singly charged y-series ions. The new MMD values were estimated as three-fold the standard deviation of the mass errors after recalibration. Finally, the mass-corrected spectra were exported as Mascot Generic File format files and resubmitted to the database search engine in order to obtain final peptide and protein identifications.

Supplementary method 2

For statistical assessment of peptide assignments the fragmentation spectra were matched against a joined target/decoy database.¹ The target part of the database containing true protein sequences was concatenated with a decoy part composed of reversed versions of these sequences. All peptide PSMs, from the forward and the reverse database, were sorted according to their score modified by subtracting the smaller of the Mascot identity and homology thresholds. The number of false positive identifications associated with a specific position P in the sorted list was estimated by doubling the number PSMs from the decoy part of the database at positions not greater than P . The position-related false discovery rate (FDR) was calculated by dividing the estimated number of false positives by the total number of PSMs at preceding positions. To address the fact that FDR itself is not a function of the underlying score (i.e. FDR can decrease with increasing position in the sorted list), the position-related FDRs were next converted to q -values, as described in.² The presented analysis was performed using a proprietary software tool implemented in Java programming language (MascotScan, <http://www.ire.pw.edu.pl/~trubel/soft/ms/mascotscan>).

Supplementary Table S5. Unified ChIP dataset. ChIP data are expressed as a mean percent of input DNA (for RNAPII and PARP1), or as an input ratio of modified histone to total histone H3 for four independent experiments. The RNAPII/H3Ac ratio was calculated for each site tested by dividing the averaged RNAPII percent of input and the H3Ac/H3 level for all time points.
