

Supplemental Figure 1. Scans of the light environment at midday in the 20 different stations where hypocotyl length was measured. To provide a more meaningful description of the light environments, the photon irradiance relative to sunlight for each wavelength under each condition averaged for four days of measurement was multiplied by the absolute photon irradiance measured for sunlight.

Supplemental Figure 2. Parametrisation, goodness-of-fit analysis and validation of the model stage I. A, Observed versus predicted values of hypocotyl length for the data used to parametrise the model. The embedded table shows the estimated coefficients of the model and their significance. B, Validation: Observed versus predicted values for an independent set of data (Yanovsky et al., 1995). The observed-predicted regression lines and the 1:1 lines (dashed) are included.

Supplemental Figure 3. Spectral irradiance of the blue and green broad-band sources.

Supplemental Table S1. Light environment at midday in the 20 different stations where hypocotyl length was measured. Photon irradiances for the indicated wavebands are expressed relative to incoming radiation and data are means and SE of four measurements.
