Supplementary Figure 1. Distribution of distance of reprogramming differentially methylated regions (R-DMRs) from CpG islands. Islands (teal) are regions that are inside, cover, or overlap more than 50% of a CpG island. Overlap (orange) are regions that overlap 0.1-50% of a CpG island. Regions denoted by (0, 500] (blue) are regions located ≤500 bp but do not overlap an island. Regions denoted by (500, 1000] (pink) are regions located >500 bp and ≤1000 bp from an island. Regions denoted by (1000, 2000] (green) are regions located >1000 bp and ≤2000 bp from an island. Regions denoted by (2000, 3000] (yellow) are regions located >2000 bp and ≤3000 bp from an island. Regions denoted by >3000 (brown) are >3000 bp from an island. Percentage are given for the CpG regions (CHARM array, null hypothesis) and reprogramming differentially methylated regions (R-DMRs) as well as the R-DMRs subdivided into hypermethylation and hypomethylation in iPS relative to fibroblast. Percentages of each class is given for (a) R-DMRs from the first experiment (n=6 for each cell type) (R-DMR panel is duplicated from Fig. 1a) and (b) R- DMRs from second experiment (n=3 for each cell type).

Supplementary Figure 2. (a-g) Examples of differential DNA methylation (upper panel) and confirmation by bisulfite pyrosequencing (lower panel). The upper panel is a plot of M value versus genomic location, where the curve represents averaged smoothed M values. Also shown in the upper panel are the location of CpG dinucleotide (black tick marks on x axis), CpG density (smoothed black line) calculated across the region using a standard density estimator, location of CpG islands (orange line), as well as gene annotation indicating the transcript (thin outer gray line), coding region (thin inner gray line), exons (filled gray box) and gene transcription directionality on the v axis (sense marked as +, antisense as -). The lower panel represents the degree of DNA methylation as measured by bisulfite pyrosequencing. The red box indicated on the x axis of the CpG density plot in the upper panel indicates the CpG sites that were measured. Reactions were done in triplicate; bars represent the mean methylation ±SD of iPS cells (pink), fibroblast (gray) and ES (blue) as well as DKO (DNMT1 and DNMT3B Double KO cell line) and HCT116 (parental colon cancer cell line) for each individual CpG site measured. (a-b) are DMRs found by comparison between iPS cells and fibroblast (n=6), (c-g) is a DMR found by comparison between iPS cells and ES cells (n=3). (a) TBX3 (T-box 3 protein), (b) HOXD3 (Homeobox D3), (c) POU3F4 (POU domain, class 3, transcription factor 4), (d) A2BP1 (ataxin 2-binding protein 1), (e) ZNF184 (zinc finger protein 184), (f) IGF1R (insulinlike growth factor 1 receptor), (g) PTPRT (protein tyrosine phosphatase, receptor type, T).

Supplementary Figure 3. Gene expression strongly correlates with reprogramming differentially methylated regions (R-DMRs) at CpG island shores. Red circles represent R-DMRs that are within 2kb from a CpG island, blue circles represent those that are more than 2kb away from a CpG island, and black circles represent log ratios for all genes not within (a) 500bp or (b) 1kb from the transcriptional start site (TSS) of an annotated gene. The \log_2 ratios of fibroblast to iPS expression were plotted against ΔM values (fibroblast minus iPS) for R-DMRs in which one of the two points had approximately no methylation. (a) DMRs that are within 500bp from a TSS of a gene. (b) DMRs that are within 1kb from a TSS of a gene.

Supplementary Table 3. Reprogramming differentially methylated regions (R-DMRs) overlap with bivalent domains. Overlap is significant in hypomethylated R-DMRs but not in hypermethylated R-DMRs.

| Madhalada. | Total | | Overlap with bivalent domai | | | |
