Table S1. A summary of mutations in HIV-1 gag, RT and nef which have been reported in the literature as conferring CTL escape and confirmed by *in vitro* tests.

In some cases the HBX2 epitope sequence differs from the author wildtype sequence and/or the B-clade ancestral sequence [S24]. These changes are shown in column 2. Note that we have not included in this list any defined escape mutations that lie in sites that differ between the author wildtype sequence and the B-clade ancestral sequence. Epitopes are ordered according to their location within the genome. The proportion of Caucasians with each HLA type is estimated from allele frequencies amongst Caucasians [36], assuming mendelian genetics. This calculation ignores linkage between alleles. ^aEpitopes AADTGHSNQ and HSNQVSQNYP are excluded from analysis of the cross-sectional data (dataset 2) and the longitudinal cohort data (dataset 4) because their HLA-restrictions were not determined. In addition, sequence data were not available from the cross-sectional study for IPLTEEAEL or SRLAFHHVAR or from the longitudinal cohort study for ETFYVDGAANR. Sequence data for CGKEGHTAR were available from neither study. ^bWhere two or more different mutations are given together with the ‘&’ sign, it indicates that an epitope containing that combination of mutations was tested and found to confer escape.
