FINAL REPORT

STUDY NUMBER 6DNDIP2

Caco-2 Permeability

SUMMARY

The bi-directional permeability of three test compounds was examined in a Caco-2 cell system. All test compounds were found to have high permeability and no significant efflux.

DATE OF ISSUE

COMPLIANCE

This study followed established practices and standard operating procedures of Absorption Systems, LP. The report is archived in a validated Scientific Data Management System. Electronic signatures comply with the regulation 21 CFR Part 11.

1. OBJECTIVE

The objective of this study was to determine the bi-directional Caco-2 permeability and efflux limited absorption potential of three test compounds.

2. PERMEABILITY, CACO-2

Caco-2 monolayers were grown to confluence on collagen-coated, microporous, polycarbonate membranes in 12-well Costar Transwell[®] plates. Details of the plates and their certification are shown below. The permeability assay buffer for the donor chamber was Hanks Balanced Salt Solution containing 10 mM HEPES and 15 mM glucose at a pH of 7.4. The buffer in the receiver chamber also contained 1% Bovine Serum Albumin (BSA). The test compound dosing concentrations were 5 μ M in the assay buffer. The cells were dosed on the apical side (A-to-B) or basolateral side (B-to-A) and incubated at 37°C with 5% CO₂ in a humidified incubator. After two hours, aliquots were taken from the receiver and donor chambers. Each determination was performed in duplicate. The Lucifer Yellow flux was also measured for each monolayer after being subjected to the test compounds to ensure no damage was inflicted to the cell monolayers during the flux period. All samples were assayed by LC/MS/MS using electrospray ionization. Analytical conditions are outlined in Attachment I. The apparent permeability, P_{app}, and percent recovery were calculated as follows:

$$P_{app} = (dC_r/dt) \times V_r/(A \times C)$$
(1)

Percent Recovery = 100 x (($V_r x C_r^{final}$) + ($V_d x C_d^{final}$))/($V_d x C_N$) (2)

where,

 dC_r/dt is the slope of the cumulative concentration in the receiver compartment versus time in μ M s⁻¹.

 V_r is the volume of the receiver compartment in cm³.

 V_d is the volume of the donor compartment in cm³.

A is the area of the cell monolayer (1.13 cm² for 12-well Transwell[®]).

 C_N is the nominal concentration of the dosing solution in μM .

C is the average of the nominal dosing concentration and the measured concentration in the donor chamber at 2 hours.

 C_r^{final} is the cumulative receiver concentration in μM at the end of the incubation period.

 $C_d^{\text{ final}}$ is the concentration of the donor in μM at the end of the incubation period.

Table 2.1 Recovery and Apparent Permeability (10⁻⁶ cm/s) of Test Compounds

^(A) Absorption Potential Classification: P_{reg} (A-to-B) $\geq 1.0 \times 10^{-6}$ cm/s:

 $\begin{array}{ll} P_{app} \, (A\mbox{-to-B}) \geq 1.0 \ x \ 10^{-6} \ \mbox{cm/s}: & \mbox{High} \\ P_{app} \, (A\mbox{-to-B}) < 0.5 \ x \ 10^{-6} \ \mbox{cm/s}: & \mbox{Low} \end{array}$

^(B) Efflux considered significant if:

 P_{app} (B-to-A) ≥ 1.0 x 10⁻⁶ cm/s and Ratio P_{app} (B-to-A) / P_{app} (A-to-B) ≥ 3.0

^(C) Low recoveries caused by non-specific binding, etc. can affect the measured permeability.

COMMENTS

The three test compounds were all classified as having a high absorption potential and having no significant efflux; their intestinal permeability is not expected to be a limiting factor for their absorption in humans.

The values marked with asterisks indicate that the cell monolayers associated with those values failed the postexperiment Lucifer Yellow integrity test (NB# AS521, pages 90-91). However, the values obtained from these monolayers were in agreement with the values obtained from the respective replicate monolayers, so the data was accepted.
