Report Issued               February 2009

Page Number                 1 of 18

<b>COMPOUND</b>	Fexinidazole
<b>SOLVENT</b>	Sterile anhydrous analytical grade dimethyl sulphoxide (DMSO)
<b>CONCENTRATION LEVELS</b>	0.8, 4, 20, 100, 350, 1000 and 5000 µg/plate.
<b>STRAINS TESTED</b>	<i>Salmonella typhimurium</i> TA98, TA98NR, TA100 and TA100NR
<b>METHODOLOGY</b>	All experimentation was performed according to the protocol, with treatments of all the tester strains being performed both in the absence and in the presence of a rat liver metabolic activation system (Aroclor 1254 induced S-9) at the concentrations specified above.
<b>RESULTS</b>	
<b>Precipitation</b>	Precipitation of the test article was observed at the highest two concentrations tested in the absence and presence of S-9.
<b>Toxicity</b>	Evidence of toxicity in the form of a slight thinning of the background bacterial lawn or a complete killing of the test bacteria was observed in strains TA98, TA98NR and TA100 following treatments at the highest two or three concentrations tested in the presence of S-9. A tailing off of the mutagenic response at 5000 µg/plate in strains TA98 and TA100NR in the absence of S-9 may also be indicative of toxicity.

**MUTAGENICITY**

Statistically significant, dose related increases in revertant numbers were observed following Fexnidazole treatments of all of the tester strains both in the absence and presence of S-9 (with the exception of strain TA98NR in the absence of S-9) when the data were analysed at the 1% level using Dunnett's test. Although significant increases in revertant numbers were observed following most treatments of strains TA98NR and TA100NR, the magnitude of these effects was substantially reduced in comparison to the respective parent strains. Treatments in the presence of S-9 increased mutagenicity and potency in all strains tested although this effect was more apparent in strains TA98NR and TA100NR. This may indicate that metabolites of different mutational specificity to the parent compound may be formed.

This screening study was considered to have provided evidence of Fexnidazole mutagenic activity in this assay system. This mutagenic activity can be attributed, at least in part, to bacterial nitroreductase enzymes.

**Lowest detectable concentration**

The lowest concentrations of Fexnidazole to give a statistically significant result when the data were analysed at the 1% level using Dunnett's test for each strain are as follows:

TA98 -S-9	350 µg/plate
TA98NR -S-9	Not applicable
TA98 +S-9	100 µg/plate
TA98NR+S-9	1000 µg/plate
TA100 -S-9	4 µg/plate
TA100NR -S-9	350 µg/plate
TA100 +S-9	4 µg/plate
TA100NR +S-9	100 µg/plate

**CONCLUSION**

It was concluded that Fexnidazole did induce mutation in *Salmonella typhimurium* strains TA98, TA100, and TA100NR in the absence and presence of S-9 and in strain TA98NR in the presence of S-9 only, when tested under the conditions employed in this screening study. These conditions included treatment at concentrations up to 5000 µg/plate, in the absence and presence of a rat liver metabolic activation system (S-9). This mutagenic activity was attributed, at least in part, to bacterial nitroreductase enzymes.

**COMMENTS**

Following treatments of strain TA100 at 1000 and 5000 µg/plate in the absence of S-9, the nature of the precipitation, along with the large number of colonies made it impossible to obtain accurate revertant counts from these plates. Therefore no counts are reported for these concentrations of TA100 in the absence of S-9 in the data tables.

## MUTATION EXPERIMENT RESULTS

### Fexinidazole: summary of mean revertant colonies (-S-9) - Experiment 1

Substance	Dose Level µg/plate	TA98	TA98NR	TA100	TA100NR
