

SUPPLEMENTAL RESULTS

C-terminal Domain of StMYB1R-1 Functions as Transcriptional Activation

To test whether StMYB1R-1 has transcriptional activity in yeast, we cloned the full-length and its deletion forms of *StMYB1R-1* in the pGBKT7 vector and introduced them into the AH109 yeast strain. Yeast strains harboring constructs containing 234 to 267 amino acids of StMYB1R-1 showed the transcriptional activity, but yeast strains harboring construct missing this domain did not (Supplemental Fig. S3). Therefore, this result indicates that the transcriptional activation domain of StMYB1R-1 exists between 234 and 267 amino acids.

Effect of *StMYB1R-1* Expression in Potato

To examine whether the expression of *StMYB1R-1* influences on potato agricultural traits, we expressed it under the control of the CaMV 35S promoter. Twenty-four independent transgenic potato lines were generated and confirmed by hygromycin selection and Northern blot analysis. Among these transgenic lines, we selected three independent transgenic lines in which the *StMYB1R-1* transgene was more expressed than in the wild type (Supplemental Fig. S5A). And 3-week-old T0 progenies grown on MS medium were transferred to plant hydroponic culture growth chambers for 1 week to increase their adaptation ability to the environmental changes in soil, and then were planted in soil and raised in a greenhouse. After cultivating for 8 weeks under normal condition in the greenhouse, the plants were analyzed for growth characteristics and tuber formation. *StMYB1R-1* overexpression in transgenic potato lines 1 and 2 showed reduced plant heights of about 5~8% compared to wild-type potato plants, but line 8 grew to a similar height as wild-type plants (Supplemental Fig. S5B and C). Analysis of morphology indicated that the leaf size, shape, and leaf number of the foliar tissue were similar between wild-type and transgenic potatoes. After cultivating for 12 weeks in the greenhouse, potato tubers from wild-type and transgenic plants were harvested

and the crop yields were compared. The tuber sizes were very diverse for single plants, but tuber numbers per potato plant were about 7 to 12, with an average of 9.2 ± 1.07 . The total tuber weight of the wild-type potatoes was about 123g, but the potatoes from transgenic lines 1, 2, and 8 weighed 109.4 g, 99.7g, and 111.8 g (Supplemental Fig. S3B and D), respectively. Although transgenic plants showed a little reduced total tuber yield (about 10 - 20%), these results suggest that the expression of *StMYB1R-1* did not significantly change growth characteristics compared to wild-type potato plants.

SUPPLEMENTAL MATERIALS AND METHODS

Data analysis of Quadruple 9-mer protein binding microarray

The distribution of all log intensities were plotted as histograms which resembled a Gaussian distribution for the left side of the mode and a heavy tailed skewed distribution for its right side of the mode. The log intensity values less than the median were fit to a Gaussian distribution and the maximum likelihood estimates of the mean, standard deviation and probabilities were obtained. In order to correct for multiple hypothesis testing, the p-values for the i-th largest individual was adjusted by multiplying $(k-i+1)$ following the Holm modification of the Bonferroni adjustment (Holm, 1979) where k is the total number of 131,072. This modification of p-value was equivalent to changing the level of significance into $\alpha/(k-i+1)$ for the i-th largest log intensity values. Because 9mer core sequences are present 9 times due to the base shift, the probe sequences with p value of median less than the significance level were selected as significant probe sequences. Among the probe sequences, the sequences containing homopolymer stretches including G stretches of more than 4 G's due to the presence of single strand region by the difficulty of double strand synthesis. The selected significant probe sequences were clustered with clustalW program and the sequence logo for the clustered sequence was generated (Crooks et al., 2004).

Supplemental Fig. S1. Nucleotide and predicted amino acid sequence of *StMYB1R-1* cDNA. Under line represents single MYB-like domain.

Supplemental Fig. S2. StMYB1R-1 localizes to the nucleus. cDNA of the *StMYB1R-1* segment cloned into the pBIN121-GFP plasmid. The constructs were transfected into the onion epidermal cells by transient bombardment assay and then were observed by fluorescence microscopy at 24 hours after transfection. GFP was used as a control.

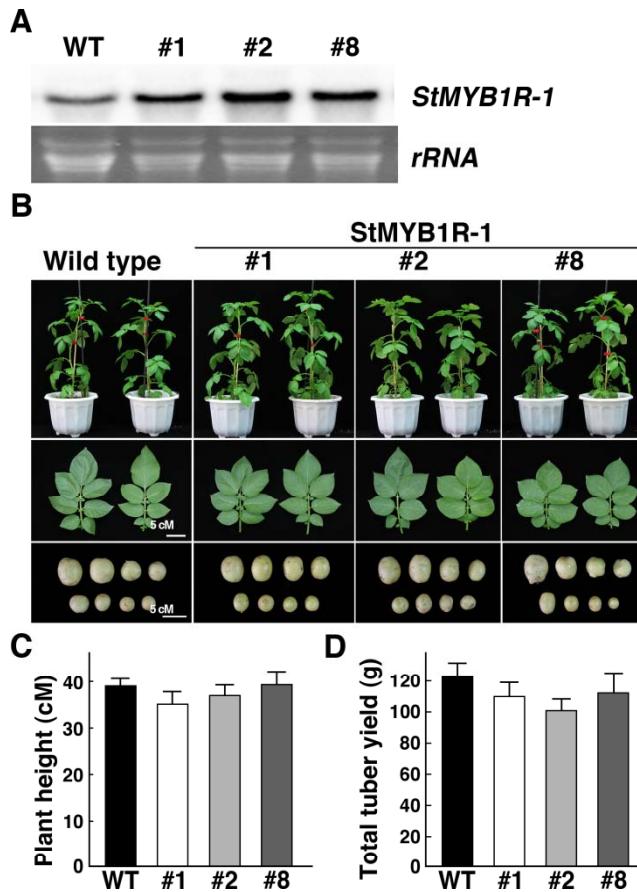

Supplemental Fig. S3. Transcriptional activation test for StMYB1R-1 in yeast. The full-length (D1) and deletion forms of StMYB1R1 (D2 to D5) were cloned into the pGBK7 vector and introduced into the AH109 yeast strain. Yeast cells harboring both genes were cultured at 30 C for overnight, diluted to an O.D.600 of 0.1, and then incubated in SC-Trp⁻ medium for 1 h. Cells were harvested by centrifugation at 3000g for 5 min and resuspended in 1 mL Z-buffer (60 mM Na₂HPO₄, 40mM NaH₂PO₄, 10 mM KCl 1 mM MgSO₄, and 50 mM β -mercaptoethanol, pH 7.0). Cell extracts were prepared, and β -galactosidase activity was measured according to the manufacturer's protocol (Clontech). The vector alone (N) was used as a negative control.

Supplemental Fig. S4. The StMYB1R-1 binds specifically to the GGATAA sequences.

(A) The sequences of oligonucleotides that were used for electrophoresis mobility shift assay. Wt; wild type sequences, M1 through M3; mutated sequences. Mutated sequences are presented in boldface. Sequences identical to the wild-type sequence are indicated with dashes.

(B) For electrophoresis mobility shift assay (EMSA), 250 ng of recombinant StMYB1R-1 protein was incubated with ³²P-labeled probe in the presence or absence of 250-fold excess cold competitor or mutated sequences (M1 to M3). Arrow indicates the positions of the StMYB1R-1 and DNA complexes.

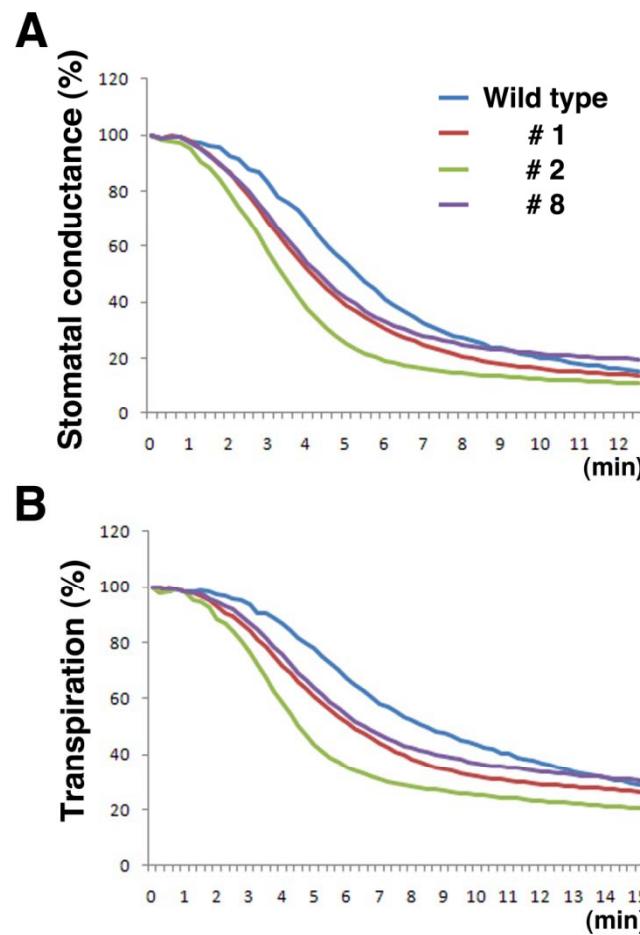

Supplemental Fig. S5. Growth characteristics of transgenic potato plants overexpressing *StMYB1R-1*.

(A) Expression of 3 independent transgenic potatoes by Northern blot analysis. Each lane was loaded with 10 µg of total RNA extracted from 3-week-old **T0** potato plantlets. The Northern blot was performed with a ^{32}P -labed *StMYB1R-1* cDNA probe. Ethidium bromide-stained rRNA was used as a RNA-loading control.

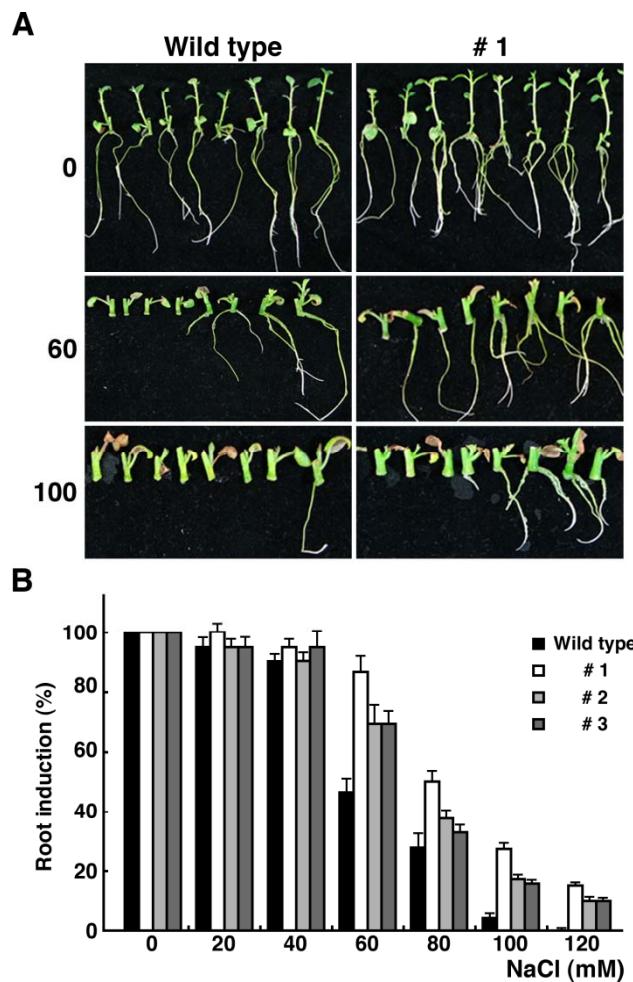

(B) and (C) Whole plant and foliar tissue of three independent lines were evaluated in 12- or 16-week-old plants grown in a greenhouse.

(D) Representative tubers of wild-type and transgenic potato plants are shown for each line that produced tubers.

Supplemental Fig. S6. Physiological characteristics of transgenic potato plants overexpressing *StMYB1R-1*.

Stomatal conductance (A) and transpiration (B) from detached leaves of 8-week-old wild-type and transgenic plant were conducted with Li-Cor LI-6400 console (Li-COR, Nebraska, USA) according to the manufacturer's recommendations (air flow; $300 \mu\text{mol s}^{-1}$, CO_2 mole fraction; $400 \mu\text{mol mol}^{-1}$, temperature; 25°C , light; $1000 \mu\text{mol m}^{-2} \text{s}^{-1}$).

Supplemental Fig. S7. Transgenic potato plants overexpressing *StMYB1R-1* are tolerant to salt stress conditions.

(A) Potato inter-node tissues were transferred to MS medium with or without NaCl (mM) and photograph were taken after 3 weeks.

(B) Root induction was determined by counting rooted or unrooted plants. $n = 3$ independent experiments (20 plants in each experiment).
