

Supplementary Information

Supplementary Methods and Discussion

Normalization

Because the raw intensity varies from cluster to cluster and based on position within the flow cell during sequencing, we tested several possible strategies to normalize for these factors before settling on using the mean intensity measured during the sequencing cycles. Reasoning that clusters containing TGASTCA motifs should have similar GCN4 binding intensity, we evaluated potential quantities for normalization by their correlation with GCN4-binding intensity in these clusters:

Normalization quantity	Pearson correlation with GCN4-binding intensity
Mean sequencing cycle intensity	0.6993
Mean sequencing cycle intensity, sum of the four channels rather than highest	0.6149
Median sequencing cycle intensity	0.6991
Last sequencing cycle intensity	0.5636
Maximum sequencing cycle intensity	0.5574

If each intensity measurement is noisy, resulting in cycle-to-cycle variability, using all of the measurements rather than the last cycle or the maximum cycle provides a more accurate estimate of cluster size.

The background intensity is calculated as the median normalized intensity over all clusters and is then subtracted from the normalized intensity of each cluster to yield the normalized intensity above background. The intensity reported in all figures is the normalized intensity above background, corrected for photobleaching.

Technical corrections

To determine the corrections needed for mapping normalization, photobleaching, and other factors, we performed a set of pilot experiments using various lengths of random oligomers.

We focused on the intensity of sequences containing the canonical GCN4 binding motif (TGASTCA, where S = C or G), reasoning that most of the variation in the intensity of these clusters would be due to technical rather than biological reasons. Variables correlating with the intensity of these clusters should therefore be corrected for.

First, we examined whether the motif position in the sequence correlated with intensity due to accessibility of different parts of the DNA. We observed no correlation between the position of the motif within the cluster sequence and the distribution of raw intensities for motif-containing clusters of size 25 (Supplementary Figure 1).

Additionally, the raw intensity of motif-containing clusters was similar for clusters containing 20-mers and 15-mers. Therefore, we performed future analyses using 25mers.

In contrast, we found that intensity of motif-containing clusters was strongly influenced by position within a particular imaging tile (data not shown). For each tile, a different spatial pattern of average intensity was observed. Therefore, we investigated normalization based on the average sequencing intensity of a cluster or the fluorescent intensity of a labeled primer. The average sequencing intensity correlated better with Gcn4p fluorescent intensity for motif-containing clusters ($R^2 = 0.48$) than the intensity of a labeled primer with Gcn4p intensity ($R^2 = 0.30$). One interpretation of this data is that the intensity measurements are inherently noisy, and that averaging over dozens of sequencing cycles provides a better measurement of cluster size and brightness than a single measurement. As a result we proceeded with analysis based on protein intensity normalized by the average sequencing cycle intensity, reducing noise due to technical reasons.

To determine the efficiency of washing and photobleaching, we performed an experiment in which we imaged a bound flow cell twice in a row without washing, and in a separate experiment imaged after washing. We found that the second round of imaging without washing reduced fluorescent intensity of TGASTCA clusters by roughly 35%, presumably due to photobleaching. The washing reduced intensity of an average cluster by roughly 65%. When we sequentially flow on increasing concentrations of Gcn4p, we do not completely wash off the protein on the flow cell, and some of what remains will be photobleached. Therefore, we correct the intensity at concentration i (C_i) using the equation:

$$C_{i,\text{corrected}} = C_i + C_i - 1 \times (1 - 65\%) \times (35\%)$$

This equation assumes that the fraction of Gcn4p remaining after washing and photobleaching will remain bound in the next set of imaging. We believe this to be a reasonable assumption, given that without this correction we observe decreasing Gcn4p signal for TGASTCA clusters at the highest concentration. This assumption is also supported by kinetics experiments showing that the off-rate of Gcn4p is quite low¹.

While 65% of intensity is washed away on average, the proportion of intensity washed away is not the same for all motifs. For example, clusters with the strongest binding 8mer, ATGACTCA, had intensity reduced by only 43%. However, because we increase the protein concentration by 5-fold at each step, after accounting for photobleaching this would affect the measured intensity by less than 3%.

Dissociation constants

The dissociation constant was first determined for the canonical motif, defined as TGACTCA for 7mers, ATGACTCA for 8mers, ATGACTCAT for 9mers, or

TATGACTCAT for 10mers. Dissociation constants were calculated by least squares fit with the hill coefficient constrained between 1 and 2 and the maximum intensity constrained to be positive, using the equation:

$$\phi_B = [\text{Gcn4p}]^h / ([\text{Gcn4p}]^h + K_d^h) \times s$$

Where ϕ_B is the fraction of DNA bound, $[\text{Gcn4p}]$ is the Gcn4p concentration, K_d is the dissociation constant of Gcn4p to the sequence, h is the Hill coefficient of binding, and s is a scaling factor for the maximum intensity. For the remaining k -mers, dissociation constants were calculated as before but with s fixed at the value determined for the consensus k -mer. The K_d was constrained to be at most 1 μM because the highest concentration of Gcn4p tested was 625 nM. Dissociation constants were determined separately for each lane, and the geometric mean and standard deviation were calculated, treating each lane as a technical replicate. To remove binding artifacts, only k -mers having a K_d less than 1 μM in at least three lanes were assigned a mean K_d of less than 1 μM .

Quality filter for lanes

We observed that one concentration value (25nM) seemed to fail for two of the lanes examined (3 and 5), because clusters containing the TGASTCA motif had no signal above background for these lanes, although strong binding was observed for the other 5 lanes. As a result, lanes 3 and 5 were not used for K_d calculations. K_d values calculated with and without lanes 3 and 5 were relatively similar (generally within 30%).

Iterative motif finding

In order to estimate K_d values for short k -mers, e.g. 8mers, from longer sequences, e.g. 25mers, one must be able to assign binding intensity to the proper k -mer. Because the oligonucleotides clustered on the flow cell were relatively short (25 nt) in our experiments, it is extremely rare for a specific k -mer sequence to occur in a cluster more than once (roughly 0.1% of the time for 7mers). Because of this fact, we employed an iterative algorithm to assign binding intensities to k -mers: For each sequence of size k , we calculated the median intensity at a Gcn4p concentration of 125nM over all clusters containing that k -mer or its reverse complement. We selected the k -mer with the highest median intensity at 125nM, determined its dissociation constant based on the median intensities, and removed all clusters containing this k -mer or its reverse complement from further calculations. We repeated this procedure iteratively until all remaining k -mers had K_d values greater than 1 μM , selecting sequences with affinity that could not be explained by occasional overlap with stronger binding sites. Due to computational limitations, we only performed the iterative removal of clusters for 9-mers containing 8mers that had K_d values less than 1 μM . Likewise, we only performed iterative removal of clusters for 10-mers containing 9-mers that had K_d values less than 1 μM .

Thus, we made the assumption that all of the intensity of the clusters containing the top k -mer comes from binding to that k -mer itself, and not to others. In the case of 8mers, for example, 95% of the time there will be not be two 8mers having K_d less than $1\mu\text{M}$ in the same cluster. After removing clusters containing this k -mer, we make the same assumption for the k -mer with the next highest median binding intensity in the remaining clusters.

Although this algorithm makes reasonable assumptions for this dataset, if the sequencing library contains longer inserts or the analysis were performed on shorter k -mers, the assumptions would not be reasonable. In this case, an expectation-maximization approach would be a more appropriate solution. The intensity of a cluster would be partitioned among its constituent k -mers in proportion to their binding affinity, and then the k -mers would be assigned an affinity based on the median binding intensity of clusters, in an iterative process. Such an algorithm could be initialized either using the iterative procedure we describe, or simply using the uncorrected median intensities.

Electrophoretic mobility shift assays

The double stranded DNA was reconstituted by mixing equimolar amounts of the two single stranded DNA molecules (Operon) in TEN buffer (10mM Tris.HCl and 1mM EDTA, pH 8.0), heating up at 90°C for 5 minutes and progressive cooling to room temperature. The dsDNA was labeled in a PNK (N.E.B.) reaction with γ - ^{32}P -ATP (Perkin Elmer). mOrange-Gcn4p dilutions were incubated for 45 minutes with labeled dsDNA at a final concentration of 1.4nM in binding buffer (1xPBS, 200 ng/mL competitor dna(Poly (I)·Poly(C), 2mg/mL BSA, 0.05% TWEEN and 10% glycerol) and resolved on a Novex 6% DNA retardation gel (Invitrogen). The gels were read on a Typhoon 9000 scanner (GE Healthcare) and the intensities of the bands measured using the ImageQuant software.

The mOrange-Gcn4p dilutions used (nM): 0, 1, 2.5, 5, 10, 25, 50, 125, 250, 1000.

EMSA values tended to underestimate the K_d somewhat relative to HiTS-FLIP, (Fig. 1f), possibly because dissociation within the gel reduces the dynamic range of the EMSA assay².

Datasets: Sequences, PBMs, PWMs, microarray data

Yeast promoter sequences were intergenic regions as annotated in the *Saccharomyces* Genome Database (SGD), up to a maximum of 500 nucleotides upstream of each gene. PBM data was downloaded from the supplementary information of reference³. A PWM was taken from reference⁴. Microarray data was downloaded from GEO⁵, ArrayExpress⁶, the Rosetta Inpharmatics web site (<http://www.rii.com/publications/2001/mcb2001Marton.html>,⁷), or the DREAM3 website (with permission of N. Clarke, <http://wiki.c2b2.columbia.edu/dream/index.php/D3c3>). Data for transgenic GCN4 expression⁵ was renormalized relative to time zero and so that the mean fold change at each time point was zero. Data for the amino acid starvation timecourse was renormalized so that the mean fold change at each time point was zero.

Occupancy scores

HiTS-FLIP promoter occupancy predictions were calculated as in⁸ by assuming that the concentration of potential binding sites is so high relative to protein that the protein is essentially always bound to some sequence. Thus, the probability of a potential binding site being occupied by a single molecule of protein is the affinity ($1/K_d$) of the site divided by the sum of the affinities of every sequence in the genome. PBM occupancies were calculated as in³, by summing the PBM binding intensity above median intensity for each 8mer in the sequence having enrichment score ≥ 0.35 . PBM binding intensities and enrichment scores were taken from the supplemental data of³.

When boxplots are used, red lines indicate medians and blue boxes indicate quartiles. Red outliers are points beyond $q_3 + 1.5(q_3 - q_1)$ or $q_1 - 1.5(q_3 - q_1)$, where q_1 and q_3 are first and third quartiles, respectively. Black whiskers extend to the furthest points that are not outliers.

For Figure 3C, genes were ranked and distributed into 40 evenly spaced bins for each gene set. Induction plotted is the mean of the \log_{10} fold-change of the genes⁷ in each bin, averaged over all bins within 5 in either axis for smoothing purposes.

Classification and correlation

Area under the curve (AUC) analysis (Fig. 3A) was performed by ranking each gene based on the predicted occupancy of its promoter and recording systematically for all occupancy score cutoffs the sensitivity and specificity. For each dataset, we defined true positives as genes that were reported as bound (in the case of the ChIP data and Ty5 data) or were induced > 2-fold (amino acid starvation data or transgenic GCN4 data). True negatives were defined as all remaining yeast genes. For the Pearson correlations (Fig. 3B), we used the top quintile of genes ranked by each respective method and correlated the predicted occupancy to the fold-change in microarray signal.

Mismatch analysis

Mismatches were considered in a 9mer context (ATGACTCA) unless otherwise stated. $\Delta\Delta G$ values for mismatches were calculated by comparing the binding affinities ($1/K_d$) of the k -mers with and without the mismatch using the formula $\Delta G = -RT \ln(K_{eq})$, with T set to 296.13 degrees Kelvin (23 degrees Celsius).

Gene ontology analysis

Gene ontology analysis was performed using NCBI's DAVID (<http://david.abcc.ncifcrf.gov/home.jsp>), limiting to level 4 or 5 GO categories. The background was genes with expression level in the top 50% at time zero in the amino acid starvation timecourse data⁹. False discovery rates reported are Benjamini-Hochberg corrected.

Washing and equilibrium

During our experiments we performed a relatively gentle wash step for 2 minutes before imaging Gcn4p bound to the DNA clusters, which should not substantially affect the equilibrium level of bound protein due to its low off-rate¹. However, for proteins with faster dissociation rates, a wash step could considerably perturb the binding equilibrium. To address this potential issue, we sought to take advantage of the GA's illumination system, which is based on total internal reflection fluorescence using evanescent wave excitation¹⁰. To test the feasibility of eliminating the wash step altogether, we performed a proof-of-concept experiment in which we skipped the wash step and imaged the clusters bound by GCN4 at 100nM. Clusters containing the top 7mer motif TGACTCA had a median intensity 13.5-fold higher than that of all the clusters, and, ranking of the top k -mers was well preserved. All 8 of the highest-affinity 7mers were shared between the experiment having a wash step and the experiment without a wash step. This observation suggests that HiTS-FLIP can detect binding at true equilibrium without a wash step at a comparable level of data quality. This property of the method differs from the PBM approach, which requires several wash steps and one dry step before the imaging is performed.

Promoter occupancy calculation

Because PBMs do not measure K_d values, it is not possible to directly apply the same calculation for promoter occupancy that was used for the HiTS-FLIP affinities. In fairness to the authors of Zhu et al. (2009), we used the same estimates for promoter occupancy that the authors used, which are presumably well-suited to their dataset. However, we sought to verify whether our method, based on the model of Stormo & Fields, would be more appropriate for PBM data as well. Under a simple model of binding on PBMs, the intensity measurements might be inversely proportional to their K_d (as assumed in Fordyce et al., Nature Biotech. 28, 970.). After converting PBM intensities to K_d estimates using this approach, we could directly compare occupancies predicted by the Stormo & Fields formalism between PBMs and HiTS-FLIP. Performing this test, the predictive accuracy of PBMs decreased from that reported in figure 3A and 3B. For example, the AUC for predicting bound genes in the Harbison et al. ChIP-Chip data fell from 0.84 to 0.68, and the AUC for predicting genes induced after amino acid starvation (Natarajan et al.) fell from 0.67 to 0.58. These observations may not be surprising, since they apply a model that assumes equilibrium binding to data collected following stringent washes.

Supplementary Tables

Supplementary Tables 1-5. HiTS-FLIP dissociation constants for 8mers through 12mers, respectively. Columns represent k -mer, K_d (nM), and log-standard deviation of K_d . Released as accompanying tab-separated value files.

Supplemental Table 6. Comparison of Gcn4p K_d measurements from literature versus K_d as measured by HiTS-FLIP for 10mer sequences.

Sequence	Literature K_d , nM (citation)	HiTS-FLIP K_d , nM
AP-1 (GATGACTCAT)	90 ± 60 (Hollenbeck & Oakley) ¹¹	12.4 ± 1.50
CRE (ATGACGTCAT)	140 ± 30 (Hollenbeck & Oakley) ¹¹	65.2 ± 6.49
CREHS (GATGACAGCT)	800 ± 200 (Hollenbeck & Oakley) ¹¹	716 ± 50.0
CRE (ATGACGTCAT)	~ 2 (Cranz et al.) ¹	65.2 ± 6.49

Supplementary Table 7. Predicted promoter occupancies using 8mer K_d values or PBM data. Columns represent systematic gene identifier, occupancy predicted by HiTS-FLIP (probability of a binding given a single Gcn4p molecule) and occupancy score calculated using PBM data³. Released as an accompanying tab-separated value file.

Supplementary Table 8:

Enrichment of GO categories in promoter sets. Enrichment analysis was done through NCBI's DAVID webserver, using the GOTERM_BP_4, GOTERM_BP_5, GOTERM_MF_4, GOTERM_MF_5 annotations and a Benjamini-Hochberg multiple-test correction. The FDR for each enrichment is in parentheses.

High-affinity sites only (n=396)	Both high- and lower-affinity sites (n=104)	Lower-affinity sites only (n=396)

Supplementary Figure Legends

Supplementary Figure 1. Binding intensity is independent of position in the sequence. For clusters containing TGASTCA, raw intensity before normalization is plotted against the starting position of the TGASTCA motif in the sequence. Low starting positions are closer to the flow cell; high starting positions are further from the flow cell. Red line indicates median, blue lines indicate quartiles. Whiskers and outliers are as explained in methods.

Supplementary Figure 2. Effects on binding of nucleotides flanking the 7mer consensus. 11mer sequences centered on the canonical 7mer match TGACTCA were divided into three categories, KRTGACTCAYM (strongest), MYTACTCAYM (weakest), and the rest (typical), where K = T or G, R = A or G, Y = T or C, and M = A or C. The K_d values for each group of 11mers are plotted. Red lines indicate median, blue lines indicate quartiles, and whiskers and outliers are as explained in methods.

Supplementary Figure 3. Gcn4p can accommodate variable spacing of half-sites. Normalized intensity is plotted for sequences containing reverse-complement half-sites (solid lines) or tandem half-sites of equivalent sequence and spacing (dashed lines). Orientation of half-sites is shown above and below sequences (blue for forward, red for reverse-complement). Overlapping halfsites (red) show the strongest binding, but only when in reverse-complement orientation. Adjacent but non-overlapping half-sites (green) still exhibited stronger binding in reverse-complement orientation compared to tandem orientation, suggesting cooperative binding as a dimer. In contrast, half-sites with a single nucleotide spacer (blue) were not bound more strongly in reverse-complement orientation, suggesting that it is impossible for the dimer to bind this sequence.

Supplementary Figure 4. EMSA experiments. Ten different dsDNA oligonucleotides (left side) with different affinities for Gcn4p were tested. The experiments were done in duplicate and the gels for both replicates are shown (right side). For all experiments, the following concentrations of mOrange-Gcn4p were used (from left to right, in nM): 0, 1, 2.5, 5, 10, 25, 50, 125, 250, 1000.

Supplementary Figure 5. Individual pairs of mismatches reveal non-independent effects of half-site binding. As in Fig. 2C and 2D, except that blue bars correspond to a 7mer having a T₁ to A mismatch from consensus (A), a T₅ to A mismatch (B), or a C₆ to A mismatch (C). Significance of differences was not assessed.

Supplementary Figure 6. Comparison between HiTS-FLIP K_d measurements and PBM enrichment scores. Each 8mer appears as a point in this plot with its enrichment score reported by³ and the K_d estimated by HiTS-FLIP.

Supplementary Figure 7. HiTS-FLIP identifies SPT15 (TBP) as a target of Gcn4p following amino acid starvation. A) Schematic of TBP promoter with strongest Gcn4p binding site candidate underlined, with mismatches to the consensus 7mer sequence in red. The percentile of the TBP promoter is compared when ranking by HiTS-FLIP predicted occupancy, PBM predicted occupancy, or PWM scores. B) TBP expression timecourse following 3-aminotriazole (3AT) addition, causing amino acid starvation, as measured by replicate microarray experiments⁹.

Supplementary Figure 8. Expression following amino acid starvation is predicted by promoter occupancy. A) All yeast genes are binned by predicted promoter occupancy using HiTS-FLIP, and boxplots indicate induction after amino acid starvation⁷. Red lines indicate median, blue box indicates quartiles, black whiskers indicate non-outlier extremes, and red dots indicate outliers. Predicted occupancy corresponds to probability that the promoter is bound at any one time at a concentration of exactly one molecule of Gcn4p per haploid genome. B) As in (A) except that occupancy is predicted using only lower-affinity k -mers ($1\mu\text{M} > K_d > 400\text{nM}$).

Supplementary Figure 9. No significant difference in strong sites between high-affinity and high- and lower- affinity promoter classes. For genes in the high-affinity only class in figure 3D ($n=396$), high- and lower- class ($n=104$), or all others, the occupancy of each promoter was predicted with a model using only high-affinity 8mers ($K_d < 400\text{nM}$). Red lines are median values, blue lines are quartiles, and whiskers and outliers are as explained in the methods.

Supplementary Figure 10. Lower-affinity Gcn4p binding sites predict induction of genes following amino acid starvation and transgenic Gcn4p induction. Genes were scored with a model using only 8-mers having $K_d < 400\text{nM}$ (high-affinity) or $400\text{nM} < K_d < 1\mu\text{M}$ (lower-affinity) and were partitioned into sets ranking in the top 500 of the high-affinity model but not the lower-affinity model, the lower- but not higher-affinity model, in both models, or in neither. A) The mean log fold change following amino acid starvation⁷ plotted for each set of genes. Error bars represent \pm one standard error. B) The mean log fold change following induction of transgenic Gcn4p⁵ for selected timepoints is plotted. Error bars represent \pm one standard error.

Supplementary Figure 11. Induction of genes with lower-affinity Gcn4p binding sites is GCN4 dependent. As in figure 3D, except that only genes having lower- but not higher-affinity Gcn4p binding sites were compared for induction after amino acid starvation in wild-type cells or GCN4 knockout cells. Error bars represent \pm one standard error. Difference at 30 minutes is significant ($p = 0.027$, paired t-test).
