

Bäumer et al. Suppl. Fig. S2:

Loss of *Inca1* correlates with increased S-phase

Cell cycle distribution of different primary wildtype (n=15) and *Inca1* knockout (n=7) MEF cell lines by propidium iodide staining. After 24 h of starvation in 0.5% FCS, the knockout cell lines had a significantly lower G1 and higher S-phase content than the wildtype cells (both $p < 0.03$, t-test). G2/M-phase was not altered. These effects were weaker or undetectable at higher serum concentrations.
