SI Materials and Methods

Competition Experiments and Analysis of Chromatography Fractions.

For competition experiments with the 5' Cy3-labeled 16-mer RNA (R16, 5' GCCACUGCUUUUCUUU 3'), Hfq (5 μ M final concentration) was preincubated with annealed RyB RNA [7 μ M RyB-OH or RyB-cP (cP, 2'-3' cyclic phosphate)] prior to the addition of Cy3-R16 RNA (10 μ M final concentration). This mixture (150 μ L) was incubated for 10 min at room temperature and subsequently analyzed by analytical size exclusion chromatography. The elution of Cy3-R16 was monitored selectively at 550 nm.

To monitor contaminating 5' truncation products of RyB that were present in the chemically synthesized sample of RyB-OH, chromatography fractions were analyzed on gel. To this end, we used unlabeled R16 and increased sample concentrations (Hfq, 10 μ M; RyB-OH or RyB-cP, 17.5 μ M; R16, 25 μ M), ensuring sufficient amounts for final analysis. The sequences of RNA addition and incubation times were identical to the experiments with Cy3-R16. Fractions (300 μ L) were split for a separate analysis of RNA (200 μ L) and protein (100 μ L) content. RNA from each fraction was phenol-extracted and ethanol-precipitated (80% final) before analysis on a denaturing 15% polyacrylamide gel, containing 8 M urea. Protein was precipitated with trichloroacetic acid (10% final) before analysis on a 15% denaturing SDS-polyacrylamide gel. For visualization, RNA was stained with methylene blue and protein with Coomassie brilliant blue according to standard protocols.

Data Collection and Refinement Procedure. Diffraction data were collected at beamline PXII (X10SA) of the Swiss Light Source (Villigen, Switzerland) at a temperature of 90 K (see Table S1 for data collection and refinement statistics). Data of *Salmonella typhimurium* (*St*) Hfq72 were recorded at 0.827 \AA on a MAR225 CCD detector, whereas data of the *St* Hfq72/U₆ complex were collected at 0.979 \AA on a PILATUS 6 M detector (1). Images were processed with XDS (2).

The structure of *St* Hfq72 was solved by molecular replacement (MR). We searched for six copies of an *Escherichia coli* Hfq monomer (derived from Protein Data Bank ID 1HK9) using PHASER MR (3) from within the CCP4 package (4). The top

solution was fed into ARP/wARP (5) for automated model (re)building. The model was finished manually in COOT (6), alternating with rounds of refinement using PHENIX (7).

Although the data for *St* Hfq72/U₆ merge perfectly well in space group P6, they were initially processed in space group P1 to allow for an entire Hfq hexamer per asymmetric unit and for asymmetry within. Molecular replacement (PHASER MR) was done with an entire *St* Hfq72 ring, followed by automated model (re)building (ARP/wARP) to remove any potential model bias. The protein model was finished manually and water molecules were added in COOT, alternating with rounds of refinement using PHENIX. Difference density was calculated from this model, clearly defining the RNA ligand. It reveals central "holes" for the rings of the base and of the ribose, and clearly defines the sugar pucker as C3' endo. However, the 5'- and 3'-terminal riboses cannot be distinguished from internal ones in this density, indicating that the termini of the hexauridine substrate fail to pack the *St* Hfq72/U₆ complexes in a register that would be reflected by the crystal symmetry. Consequently, we merged the data in space group P6, corresponding to one Hfq monomer per asymmetric unit and refined the uridine ligand with covalent bonds to its nucleotide neighbors and with a phosphate occupancy of 5/6. This procedure leads to a circular, sixfold symmetric model for the entire hexauridine ligand. The absence of significant residual density indicates that the 5'- and 3'-terminal nucleotides are indeed oriented very similarly to their internal counterparts, and the refinement statistics show an excellent quality of the model. Thiocyanate ions were assigned based on the cone-shaped difference density, on suitable coordination distances, and on crystallographic evidence (i.e., refinement leads to temperature factors that are similar to the surrounding residues and to a good agreement with the crystallographic data).

Final refinement rounds for both structures were done in PHENIX. The refinement protocol included hydrogen atoms, anisotropic B factors for all non-hydrogen atoms, occupancy refinement of atoms in alternative conformations, and target weight optimization. Stereochemical properties were analyzed with MOLPROBITY (8) and WHATCHECK (9), and structure figures were generated in PYMOL (<http://pymol.org/>).

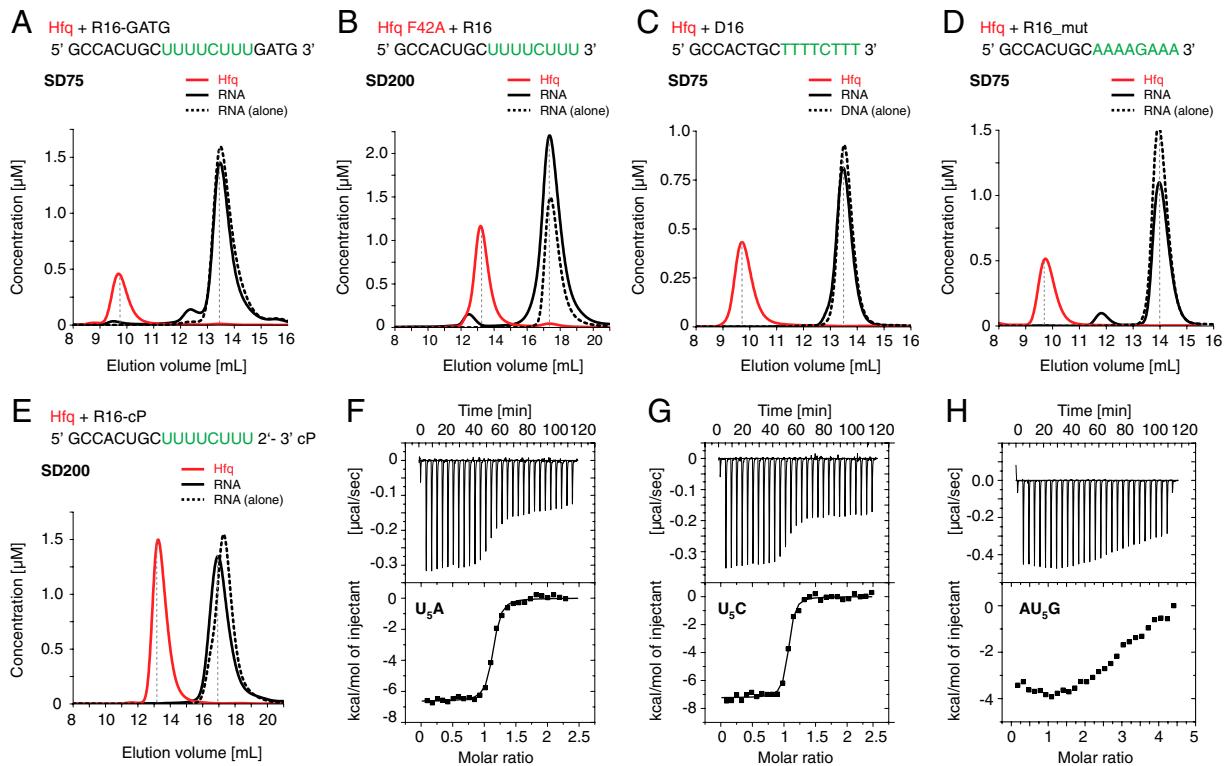

Fig. S1. Specificity of the proximal RNA binding site of *St* Hfq (*A–E*) Analytical size exclusion chromatography of Hfq (red, solid lines, 10 μM at start) in the presence of nucleic acid substrate (black, solid lines, 15 μM at start). Elution profiles show apparent concentrations for hexameric Hfq₆ rings and nucleic acid, calculated from the relative absorption properties of the components. Elution profiles for nucleic acid substrate alone (black, dashed lines, 15 μM at start) are superimposed. R16 RNA forms a stable equimolar complex with *St* Hfq₆ rings (see Fig. 1*B*), whereas the 3' extension by a GATG sequence (*A*, R16_GATG) abolishes Hfq-binding as well as a mutation of the proximal RNA binding site (*B*, Hfq F42A). Furthermore, a DNA derivative of R16 fails to interact (*C*, D16), and complex formation is prevented also by other modifications of the RNA 3' end. These are the mutation of the 3'-terminal uridines (*D*, R16_mut) and the terminal addition of a 2'-3' cyclic phosphate (*E*, R16-cP). SD200, Superdex200 resin; SD75, Superdex75 resin. (*F–H*) Isothermal titration calorimetry with hexanucleotide substrates. Individual titration experiments with U₅A (*F*) and U₅C (*G*) substrates fit a model with a single high-affinity binding site (for analysis, see Fig. 1*D*), whereas a previously published (1) AU₅G substrate (*H*) does not. Upper panels show thermal power removed to maintain a constant temperature in the sample cell, recorded over the time of multiple RNA ligand injections until saturation. Lower panels show integrated binding enthalpy associated with every injection, plotted against the molar ratio of RNA over Hfq.

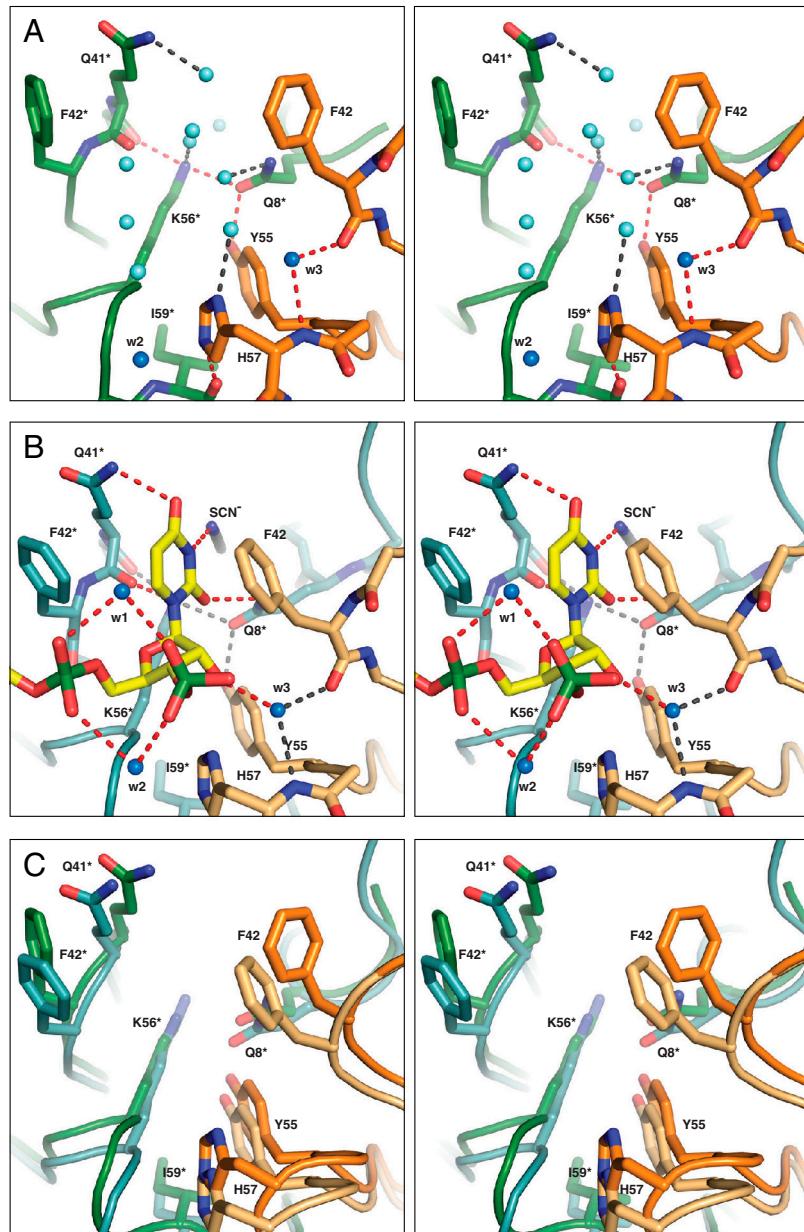

Fig. S2. Structural details of the RNA binding pocket in *St Hfq* (stereo). (A) Structure of the binding pocket in the absence of ligand (*St Hfq*72, apo-structure). Hydrogen bonds remaining upon ligand binding are red; displaced water molecules are cyan. (B) Structure of the binding pocket in the presence of ligand (*St Hfq*72/U₆). Newly established hydrogen bonds are red. (C) Superposition of the apo- and ligand-bound structures (ligands and water molecules removed), illustrating the adjustments of individual residues. RNA and important amino acids are shown as sticks, water molecules as spheres, and hydrogen bonds as dashed lines. Nitrogen, blue; oxygen, red; sulfur, gray; phosphorus, green.

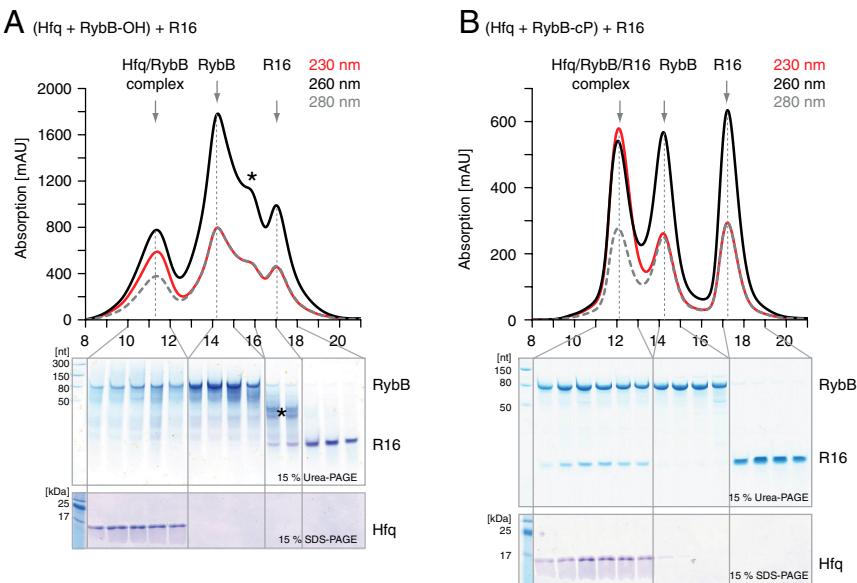

Fig. S3. Competition between an sRNA (RybB) and the R16 RNA oligonucleotide. Analytical size exclusion chromatography of Hfq in the presence of RybB RNA and of unlabeled R16 RNA. Elution volumes are indicated by gray vertical lines, together with the molecular species. Eluted fractions were split and analyzed separately for their RNA (top gel) and protein content (bottom gel). (A) Hfq₆ rings (10 μM) in the presence of RybB-OH (17.5 μM) and R16 (25 μM). Chemically synthesized RybB-OH has a free 3' hydroxyl group and elutes with trailing peaks (5' truncation products resulting from chemical synthesis, marked by an asterisk). RybB-OH coelutes with Hfq₆ and prevents R16 from binding Hfq₆. R16 does not interact with RybB-OH. (B) Hfq₆ rings (10 μM) in the presence of RybB-cP (17.5 μM) and R16 (25 μM). RybB-cP terminates in a 2'-3' cyclic phosphate, but still coelutes with Hfq₆. However, it allows the coassociation of R16 to form a ternary complex (see Fig. 3).

of blastic reads from Hfq copurification (Hfq cop), Control. Number of unstable cDNA reads obtained from control immunoprecipitation (Control cop). Enrichment enrichment factor calculated by the number of terminal sequences in upper case letters. Terminal uridines are highlighted in bold when mostly single-stranded (six positions, tolerating C, A). Guanosines potentially interfering with Hfq binding are italicized. Nucleotides that are base-paired as part of the terminator hairpin are underlined. For sRNAs with processed 3' ends, all base-paired nucleotides are underlined

^aCompared to the enrichment on Hfq, only previously named sRNAs with an enrichment of >7.5 (plus rnbB-1) are listed. sRNAs are sorted according to the enrichment on Hfq. For a microarray analysis in *Escherichia coli*, sRNAs with a base-pairing potential as a pair or tri-cinematocystic acid precursor are included.

¹⁵ and 31 ends are according to Li et al. (1998) (3).
