

Supplementary Figure 4: Detection of anti-AAV capsid IgG antibodies after IM administration of rAAV-Luc vectors. Mice were administered 1×10^{10} rAAV12-Luc or rAAV2-Luc vector particles by IM route. Anti-AAV capsid protein IgG titers were measured four weeks post initial rAAV12-Luc and rAAV2-Luc vector administration by ELISA as described in methods. Optical density values of naïve serum controls were subtracted from overall values. Error bars represent the mean optical density reading + SEM, where $n = 3$. Statistical comparison was performed by unpaired t-test.
