Figure S1. Histology of progressing plasma cell tumors in pristane oil-treated iMyc mice. To identify and enumerate plasma cells *in situ*, paraffin-embedded formalin-fixed tissue sections of oil granulomas analyzed at early (day 7; panels A and B), middle (day 39, panels C and D) and late (day 107; panels E and F) times after ip injection of pristane were sectioned and either stained with hematoxylin and eosin (H&E; panels A, C and E) or immunolabeled with antibody to mouse immunoglobulin kappa light chains followed by counterstaining with hematoxylin (panels B, D and F). Cytoplasmic light chains were visualized using vector red (panels B and F) or diaminobenzidine (DAB; panel D) as substrates. All images were acquired with a 40X objective.

Figure S2. Focused analysis of gene expression changes during tumor progression in initial study. Heat map of significantly changed genes during tumor progression in LMD-isolated PC samples or non-dissected whole-tissue OG samples. A total of 1385 gene probes were selected by ANOVA and subjected to unsupervised hierarchical cluster analysis.

Figure S3. Combined analysis of gene expression changes during tumor progression in initial study (Study 1) and validation study (Study 2). Panel A depicts a heat map that resulted from unsupervised hierarchical cluster analysis of RNAs from PC and OG samples, using 5,521 variance-filtered genes (showing the top 25% variance and of which more than 20% of expression values have at least 1.5-fold change in either direction from the gene's median value). Panel B depicts the clustering of the 1205 ANOVA-revealed gene probes ($p < 0.001$) that showed significant differences in the PC samples from both experiments. The samples are ordered chronologically according to the day after which PCT development had been induced by ip administration of pristane.

Figure S4. Time courses of expression levels of five selected ANOVA-revealed OG genes up- or downregulated in tissues containing frank tumor cells compared to tissues harboring premalignant tumor precursors. Log₂-transformed mean gene expression levels (horizontal lines) and individual gene expression levels (dots) at indicated times post tumor induction with pristane are plotted for Study 1 (Initial study) in the left column and Study 2 (Validation study) in the center column. The results of statistical comparisons (two-tailed t-test) of mean expression levels of combined tumor precursor samples (white columns; days 7-33 in case of Study 1 [n=9]; days 7-49 in case of Study 2 [n=12]) and tumor samples (black columns; day 104 in case of Study 1 [n=3]; day 105 in case of Study 2 [n=3]) are indicated as p values in the right column. *Eif2ak3*, eukaryotic translation initiation factor 2 alpha kinase 3; *Ccl11*, chemokine (C-C motif) ligand 11; *Cd36*, CD36 antigen; *Ear1*, eosinophil-associated, ribonuclease A family, member 1; *Rab34*, RAB34 member of RAS oncogene family.

Figure S5. Genetic pathway maps implicated in PCT progression by Metacore

(GeneGo) analysis. Statistically significant maps detected at a false discovery rate (FDR) of 10^{-4} in the PC samples from Study 2 (n=26) and Study 1 (n=7) are presented in panels A and B, respectively. Maps are ordered from top to bottom according to level of significance, which is expressed as negative logarithmic *p* value. Panel C depicts the top three significant maps at FDR 10^{-3} that exhibit the greatest deal of similarity between Studies 1 and 2. The maps are indicated in bright colors. Also included are three highly similar maps that are, however, not significant at FDR 10^{-3} and, therefore, indicated in dull colors.

Figure S6. Genes involved in mouse PCT progression in mouse are highly enriched in a gene set that includes human MGUS, SMM and MM).

A) Human Heat Map. Heat map of significantly differentially expressed genes (FDR < 5%) in 115 cases from the Mayo Clinic Patient Dataset deposited at the Multiple Myeloma Genomics Portal (MMGP), Broad Institute, Cambridge, Massachusetts (<http://www.broadinstitute.org/mmgp/>): MGUS (n=22), SMM (n=24) and MM (n=69). RNA samples from CD138⁺ plasma cells from patient bone marrows had been hybridized to Affymetrix U133A microarrays and gene expression determined according to established procedures. RMA-normalized data files were transferred from the MMGP website to the University of Iowa, where ANOVA analysis of the 18,737 genes that have a mouse counterpart with the identical gene name revealed 2,292 unique, annotated genes that varied significantly among the MGUS, SMM and MM groups. These genes were represented by 2,963 gene probes, which were subjected to unsupervised hierarchical cluster analysis that produced the presented heat map. Relapsed MM, which is also included in the Mayo Clinic Patient Dataset, was excluded here because of uncertainty whether gene expression changes reflected tumor progression or treatment effects.

B) Venn diagram on the origin and number of mouse genes used for cross-species comparison with the Mayo Clinic Patient Dataset. The mouse ANOVA-PC-gene probe sets from Study 1 and Study 2 (corrected for genes also found in OG stroma, see Figs. 2B and 3B for details) were merged to identify probes that varied significantly in the course of PCT progression in *either* Study 1 *or* Study 2 (“combined” probe set) or in *both* Study 1 *and* Study 2 (“in-common” probe set). The merged dataset was found to be populated by more than 4,000 gene probes that represented 2,218 “combined,” unique, annotated mouse genes with synonymous human counterparts. These “combined” genes were used for the statistical comparison with the Mayo Clinic Patient Dataset presented in panel C. The merged dataset also contained 386 gene probes that represented 315 “in-common,” unique, annotated mouse genes with synonymous homologues in the human genome. These “in-common” mouse genes were used for the statistical analysis of the Mayo Clinic Patient Dataset as depicted in panel D and displayed as a heat map in panel E.

C) Statistical analysis of the enrichment of “combined” mouse PCT progression genes in the Mayo Clinic Patient Dataset. EASE [Expression Analysis Systematic Explorer, Hosack, et al., *Genome Biol* **4**, R70 (2003)] was employed to determine whether genes that were found to be variably expressed during progression of mouse PCT were also statistically overrepresented in the human MGUS-SMM-MM dataset presented in panel A. EASE uses concepts very similar to those employed in genetic pathway enrichment analyses; it calculates *p* values to indicate the statistical strength of biologic associations. 294 (12.8%) of the 2,218 unique, “combined” mouse LMD-PC genes, which were shown by ANOVA to vary significantly during the course of mouse PCT progression in *either* Study 1 *or* Study 2, were also found within the set of 2,292 human genes from the Mayo Clinic. This overlap was significant (*p* = 0.00285) using the EASE software tool for statistical comparison.

D) Statistical analysis of the enrichment of “in-common” mouse PCT progression genes in the Mayo Clinic Patient Dataset. In a more stringent statistical analysis compared to that presented in panel C, 40 (12.7%) of the 315 “in-common” mouse LMD-PC genes – revealed by ANOVA to change significantly during mouse PCT progression in *both* Study 1 *and* Study 2 – were also found within the set of 2,292 human genes from the Mayo Clinic. This overlap was highly significant (*p* = 2.05 x 10⁻¹⁵) by EASE, in keeping with the expectation that a 12.7% overlap of a set of 315 genes with a 2,292-gene set is much less likely to occur by chance than a 12.8% overlap of a set of 2,218 genes with the same 2,292-gene set.

E) Cross-species heat map visualizing the enrichment of “in-common” mouse PCT progression genes in the Mayo Clinic Patient Dataset. The human counterparts of the 315 mouse genes indicated in panel D were used to re-analyze the Mayo Clinic Dataset in an attempt to reveal heretofore unknown associations in the human samples. The results of unsupervised hierarchical clustering are displayed as a heat map. Two portions of the heat map (boxed in white) are expanded on the right and demonstrate examples of apparent up-regulation of 12 unique genes in MGUS relative to SMM and MM (top right; represented by 15 gene probes) and 7 genes upregulated in SMM/MM relative to MGUS (represented by 15 gene probes; bottom right). More in-depth studies are warranted to validate these putative myeloma progression genes and understand the underlying biology.
