

The nucleotide sequence of *leuA* from *Salmonella typhimurium*

Ezio Ricca⁺ and Joseph M. Calvo*

Section of Biochemistry, Molecular and Cell Biology, Cornell University, Ithaca, NY 14853, USA

Submitted January 29, 1990

EMBL accession no. X51583

The *leuABCD* operon of *Salmonella typhimurium* encodes enzymes involved in the conversion of α -ketoisovalerate to leucine (1). *leuA* encodes α -isopropylmalate synthase (EC 4.1.3.12) (2, 3), an enzyme composed of four identical subunits (4). Below is shown the nucleotide sequence of *leuA*, together with the deduced amino acid sequence of the longest open reading frame. The known sequence of 10 amino acids at the N terminus (5) and the known C-terminal valine (6) are correctly predicted by the nucleotide sequence. The predicted size of the *leuA* polypeptide (522 amino acids, 57,574 daltons) is similar to experimentally-obtained values (55,600, ref. 7; 52,000, ref. 8).

ACKNOWLEDGEMENT

This study was supported by grant R01 GM38898 from the National Institutes of Health.
