Figure S1 Amino acid sequence analysis of seven OccK subfamily members. (A) Phylogenetic tree generated by ClustalW2 (Version 2.1, The European Bioinformatics Institute, UK) and (B) Sequence homology analysis generated by Clustal Omega (Version 1.0.3, The European Bioinformatics Institute, UK), where conserved sites are marked with '*', ':', or '.' at the bottom of the sequences. An asterisk (*) indicates positions which have a single, invariant residue. A colon (:) indicates conservation between groups of strongly similar properties (scoring > 0.5 in the Gonnet PAM 250 matrix). A period (.) indicates conservation between groups of weakly similar properties (scoring =< 0.5 in the Gonnet PAM 250 matrix). The β -barrel regions are highlighted in yellow. The charged amino acids located near the central constriction are marked in red. Large extracellular loops L3, L4, and L7, which are folded back into the channel lumen, are indicated by horizontal arrows.

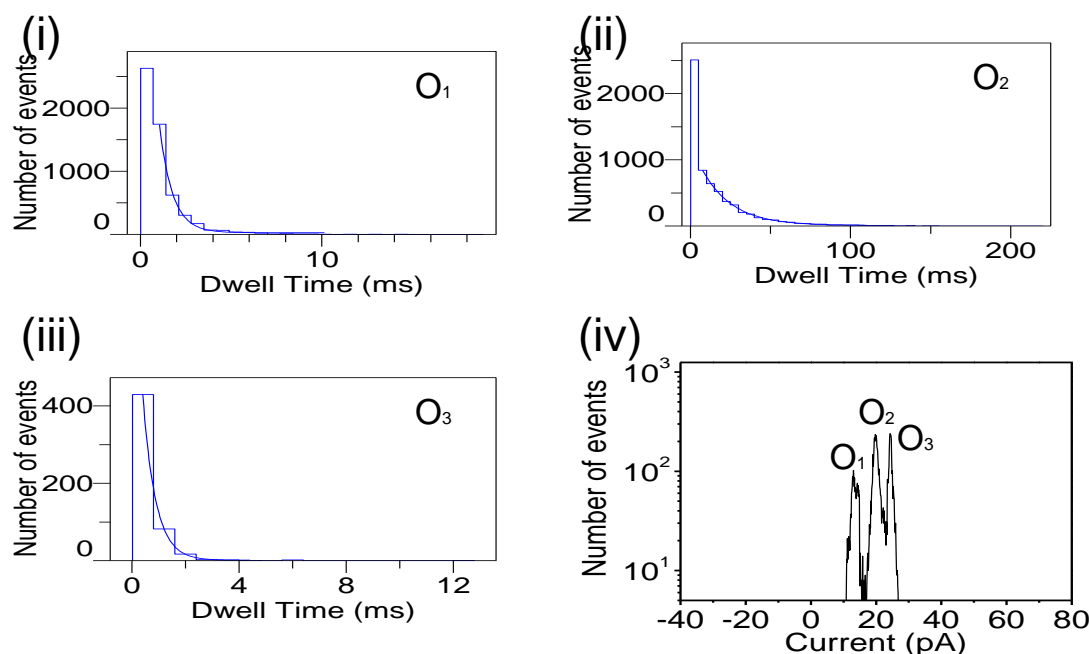

Figure S2 The single-channel sub-state transition analyses of the OccK subfamily members. (A) OccK1, **(B)** OccK2, **(C)** OccK4, **(D)** OccK5, **(E)** OccK6 and **(F)** OccK7. For **(A)**, **(E)** and **(F)**, (i),(ii), and (iii) are the dwell time histograms of the O₁, O₂, and O₃ open sub-states, respectively. In these cases, (iv) represent the fitted current amplitude histograms, indicating the number of events of each open sub-state. For **(B)**, **(C)**, and **(D)**, (i) and (ii) are the dwell time histograms of the O₁ and O₂ open sub-states, whereas (iii) are the fitted current amplitude histograms. Data were collected in 1M KCl, 10 mM potassium phosphate, pH=7.4, and at a transmembrane potential of +60 mV. For OccK4 and OccK6, the traces were low-pass Bessel filtered at 5 kHz. In the case of the other protein channels, we used a filtering frequency of 2 kHz. All the dwell time histograms are fitted to a single-exponential distribution, as judged by log likelihood ratio (LLR) tests with a confidence level of 95% (*I*;2). The fitting results of the dwell time histograms were the following: τ_{O_1} (OccK1) = 2.37 ± 0.06 ms; τ_{O_2} (OccK1) = 6.09 ± 0.08 ms; τ_{O_3} (OccK1) = 4.79 ± 0.06 ms; τ_{O_1} (OccK2) = 0.38 ± 0.02 ms; τ_{O_2} (OccK2) = 19.16 ± 0.23 ms; τ_{O_3} (OccK2) = 0.56 ± 0.02 ms; τ_{O_1} (OccK4) = 129 ± 6 ms; τ_{O_2} (OccK4) = 0.14 ± 0.01 ms; τ_{O_1} (OccK5) = 29.1 ± 0.4 pS; τ_{O_2} (OccK5) = 0.12 ± 0.01 ms; τ_{O_1} (OccK6) = 219 ± 20 ms; τ_{O_2} (OccK6) = 1.11 ± 0.03 ms; τ_{O_1} (OccK7) = 0.72 ± 0.03 ms; τ_{O_2} (OccK7) = 19.1 ± 0.3 ms; τ_{O_3} (OccK7) = 0.48 ± 0.01 ms.

A three-open sub-state kinetic model for the current fluctuations of the OccK proteins

Using standard formalisms of chemical kinetics for single-molecule fluctuations of the OccK protein channel (3), we have the following system of partial differential equations (4-6):

$$\begin{aligned}\frac{dP_{O_1}}{dt} &= -k_{O_1 \rightarrow O_2} P_{O_1} + k_{O_2 \rightarrow O_1} P_{O_2} \\ \frac{dP_{O_2}}{dt} &= +k_{O_1 \rightarrow O_2} P_{O_1} - k_{O_2 \rightarrow O_1} P_{O_2} + k_{O_3 \rightarrow O_2} P_{O_3} - k_{O_2 \rightarrow O_3} P_{O_2} \\ \frac{dP_{O_3}}{dt} &= -k_{O_3 \rightarrow O_2} P_{O_3} + k_{O_2 \rightarrow O_3} P_{O_2}\end{aligned}\tag{S1}$$

where P_{O_1} , P_{O_2} and P_{O_3} are the probabilities to occupy the O_1 , O_2 and O_3 sub-states, respectively. These probabilities are defined by the following expressions (4-6):

$$\begin{aligned}P_{O_1} &= \frac{T_{O_1}}{T} = \frac{N_{O_1} \tau_{O_1}}{T} = f_{O_1} \tau_{O_1} \\ P_{O_2} &= \frac{T_{O_2}}{T} = \frac{N_{O_2} \tau_{O_2}}{T} = (f_{O_1} + f_{O_3}) \tau_{O_2} \\ P_{O_3} &= \frac{T_{O_3}}{T} = \frac{N_{O_3} \tau_{O_3}}{T} = f_{O_3} \tau_{O_3}\end{aligned}\tag{S2}$$

Here, T_{O_1} , T_{O_2} and T_{O_3} are the total times occupied by the O_1 , O_2 and O_3 sub-states, respectively. N_{O_1} , N_{O_2} and N_{O_3} are the total recorded events that correspond to the O_1 , O_2 and O_3 sub-states, respectively. T indicates the total recording time. f and τ denote the event frequency and the average dwell time for a well-defined sub-state, respectively. The equations (S2) show two components for the O_2 state, corresponding to transitions toward the O_1 and O_3 sub-states. In other words, the well made by the O_2 sub-state is flanked by two barriers for reaching the O_1 and O_3 sub-states.

The rates for reaching the O_1 and O_3 sub-states are just the corresponding event frequencies, which are normalized to the P_{O_2} probability:

$$\begin{aligned}k_{O_2 \rightarrow O_1} &= \frac{f_{O_1}}{P_{O_2}} = \frac{f_{O_1}}{1 - f_{O_1} \tau_{O_1} - f_{O_3} \tau_{O_3}} \\ k_{O_2 \rightarrow O_3} &= \frac{f_{O_3}}{P_{O_2}} = \frac{f_{O_3}}{1 - f_{O_1} \tau_{O_1} - f_{O_3} \tau_{O_3}}\end{aligned}\tag{S3}$$

At equilibrium, the partial derivatives of equations (S1) are zero, since the event probabilities are constant. Therefore,

$$\begin{aligned}k_{O_1 \rightarrow O_2} &= \frac{1}{\tau_{O_1}} \\ k_{O_3 \rightarrow O_2} &= \frac{1}{\tau_{O_3}}\end{aligned}\tag{S4}$$

The equations (S3) and (S4) indicate that the four rates, which describe the kinetic scheme with three open sub-states, can be calculated using the event frequencies and the average dwell times of the flanked O_1 and O_3 sub-states. In addition, the equations (S3) and (S4) confirm the general rule that the average dwell time in a particular sub-state is given by the reciprocal of the sum of the kinetic rate constants for the transitions occurring away from that respective sub-state (3;7-9):

$$\frac{1}{\tau_{O_2}} = k_{O_2 \rightarrow O_1} + k_{O_2 \rightarrow O_3}\tag{S5}$$

Table S1: The standard free energies corresponding to various gating transitions of the Occk1 protein. (A) 1 M KCl; (B) 2 M KCl; (C) 3 M KCl; (D) 4 M KCl. The buffer solution contained 10 mM potassium phosphate, pH 8.0. All standard free energy (ΔG) values are given in $k_B T$. Data represent averages \pm SDs over a number of at least three distinct single-channel electrical recordings.
