Figure S1. Switch frequency in individual sharks.

Panel A. Switched Ig in shark pups. **Left.** RNA was isolated from non-immunized pups AQ, LA, TH, and EC and immunized sharks JS (HEL) and GR (Ebola virus). First strand cDNA was primed with a universal CH2 primer (CH2-3') and PCR was performed with G2A/B-specific reverse primer (G2CH2R) and universal forward primer (V1-5) for 30 cycles. The PCR products were incubated with (+) and without BstEII (0) and electrophoresed. The filter was incubated with a probe detecting only the VH, and the lane between 8 and 9 shows marks for the hybridizing PCR fragments sized ~777 bp, ~647 bp, and ~322 bp. **Right.** Predicted PCR products and results of their cleavage with BstEII. Non switched G2B (green) contains no BstEII sites whereas non switched G2A (blue) contains one in JH segment and one in C μ 2 (arrows). Digestion with BstEII generates a ~322 bp G2A band and ~777 bp G2B band detected by vh probe (as underlined). The ~647 bp band found in adults but not in pups indicates few G2 sequences are switched (or mutated) in very young animals.

Panel B. Frequency of switching to G2A alone or to G2B alone. **Left.** RNA was isolated from non-immunized neonate AQ (lane 1-3), and adult 33 (4-6) and from immunized sharks GR (lane 7-9), JS (lane 10-12), and PI (lane 13-15). The organ source was spleen in all cases except shark-33 epigonal organ. First strand cDNA was primed with G2A or G2B-specific oligonucleotide (G2A-C2a, G2B-C2a) and PCR was performed respectively with G2A or G2B-specific reverse primers (G2A-C2b, G2B-C2b) and universal forward primers (V1-5) for 35 cycles. The PCR products were standardized for uniform signal intensity to vh probe and these adjusted amounts were incubated with (+) and without BstEII (0) and electrophoresed. The G2B PCR products were also incubated without BstEII, but are not shown. The filter was hybridized with a probe detecting only the VH. **Right.** Predicted PCR products and results of their cleavage with BstEII. Non-switched G2B (green) contains no BstEII sites whereas non switched G2A (blue) contains one in JH segment (lighter shade) and one in C μ 2. Digestion with BstEII generates a ~322 bp band with G2A and ~777 bp G2B detected by vh probe in non switched sequences. Left. The ~647 bp band in lanes 5, 8, 11, and 14 indicates the absence of the BstEII site in the JH of G2A, either a mutation or non-G2A VDJ (tan) that is from G2B, G3, or G4 (see Figure 3, lack of BstEII sites). Right. A ~322 bp band appearing in lanes 3, 6, 9, 12 or 15 would have indicated a non-G2B VDJ that is from G2A, G1 or G5 (see Figure 3, presence of BstEII sites). The BstEII fragment detectable by the probe is underlined.

Panel C-E. Switching to G5 constant region. **C.** RNA was isolated from neonate AQ (lane 1, 2), adults 33 (3, 4), GR (5, 6), and JS (7, 8). First strand cDNA was primed with G5C region primer (G5C2) and PCR was performed universal forward primers (V1-5) and G5 C region primer (G5CH1R) for 40 cycles. The PCR products were incubated with and without Bam HI for one hour and electrophoresed. The filter was hybridized with a probe detecting only the VH. Arrows in lanes 4, 6 and 8 indicate sequences not cleaved by Bam HI, the ~600 bp fragments that isolated and cloned. **D.** G5 PCR products digested with Bam HI. Digestion of non-rearranged (GL G5) transcript in shark-AQ is depicted at the top. Rearranged sequences were cleaved into ~503 bp and 97 bp fragments. G5 with mutated Bam HI sites or non-G5 VDJ (switched) did not cleave and these were isolated (arrows) by gel extraction and cloned into pGEM. **E.** Tabulation of results for switch to G5 C region from three individuals. After BamHI digestion the 600 bp resistant fragments were cloned and analyzed. Of the portion that was negative for the BamHI site on re-screening, some sequences proved to be mutants and others non-G5 (switched) VDJ. In the neonate AQ the 600 bp fragment that remained after Bam HI digestion proved to be almost entirely non-rearranged. Accession numbers of switched sequences from JS are (GQ359852, GQ359856, GQ359858, GQ282627) and from GR are (GQ359826-GQ359831, GQ359848-GQ359851).

Figure S2. CDR3 and J/C junctions of switched VDJ.

Top, RT-PCR was performed to raise switched Ig sequences from several adults (GR, JS, PI). The first strand primers are listed, with the approximate positions below the H chain transcript. For PCR, the forward primer was in the leader or VH FR1 and the reverse in the C region. Only the CDR3 and J/C splice are shown below; some sequences were entered into GenBank, as indicated.

Bottom, I-XI, sequences are compared to the IgH subfamily (identities highlighted in yellow in VDJ and C in pink). Mutations are marked in blue; red indicates non-productive sequences. Sequences shown as sharing CDR3 differ in mutations throughout VDJ. Sets I-XI: [I] G4A VDJ-G5 C region. First strand primed with G5-specific G5C2. (A) PCR with universal V1-5 and specific G5CH1R. Fragments of ~600 bp were digested with BamHI; non-digested fragments were cloned into pGEM and analyzed. (B) Direct PCR was done with combination G4L and G5CH1R. [II] G4CG VDJ-G5 C region. See legend to I. [III] G1 VDJ to G5 C region. Direct PCR primer V-1 and G5CH1R. [IV] G2A VDJ to G5 C region. See legend to I. [V] G2B VDJ to G5 C region. See legend to I. [VI] G1 VDJ to G2A C region. First strand primed with G2A-C2a. Direct PCR primers V-1 and G2A-C2b [VII] G1 VDJ to G2B C region. First strand primed with G2B-C2a. Direct PCR with primers V-1 and G2B-C2b. [VIII] G5 VDJ to G2A C region. First strand primed with G2A-C2a. Direct PCR with G5L2 and G2A-C2b, expected size ~840 bp. [IX] G5 VDJ to G2B C region. First strand primed with G2B-C2a. Direct PCR with G5L2 and G2B-C2b, expected size about 840 bp. [X] G5 VDJ to G4CG C region. First strand primed with G4CH1A. Direct PCR with G5L2 and G4CH1B, expected size ~552 bp. [XI] G5 VDJ to G4A C region.

Fig. S3. Clonally related, switched Ig sequences.

A. Non-productive G5 VDJ switched to G4CG C region. G5 VDJ switched to G4 C region were amplified from shark-GR cDNA with subfamily-specific primers directed to the G5 leader (G5L2) and G4 C region (G4CH1B). Two out-of-frame VDJ were related, sharing a common CDR3; clones G4G5-142 and -38 shared a deletion (dashes) and duplication (arrow and sequence) in FR1, a deletion in CDR2 (gapped with dashes) and multiple mutations. The VDJ are out-of-frame, but mutations that would have otherwise lead to amino acid substitutions are indicated from CDR1 to FR3. Asterisk in Y/* indicates mutation tyrosine to stop codon. Accession numbers JQ272819-20.

B. Five switched sequences isolated from the shark-GR epigonal organ cDNA library. Five cDNAs sharing one CDR3 are compared with reference GL sequences from G2A and G2B. See Fig. 2B legend. Mutant nucleotides common to all five cDNAs are in upper case; when there is more than one change at a position, the second is marked in gray. Mutations leading to amino acid substitutions are indicated beneath codons.

B. Insertion (I58, I41)

Figure S4. Switch junctions.

Top, diagram of primers used (separately) for first strand cDNA and their locations along the J-C intron (position 1 is first position after JH). Spleen (OMG5, G512) and epigonal organ (OMG) RNA from shark-GR were used. PCR primer pair G4L/G511 amplify fragments of about ~900 bp and G4 VDJ joined to G5 intron were obtained. Only the switch junction is shown for most of the sequences.

Bottom, alignments with G4 and G5. Positions shared with G4 highlighted in yellow, shared with G5 in pink, mutations in blue. The intron positions are numbered in all sequences. Arrow indicates where the G4A sequence identity ceases; hotspot motifs RGYW/WRCY are underlined in its vicinity or that of G5. Sequences were entered into Genbank, Accession numbers JQ272797-JQ272818.

B. Two sequences, I58 and I41, that share CDR3 are compared to G4 and G5. B. I58, I41. Two sequences share CDR3 (as indicated), some mutations (in blue) and switch point at position 20.

C. I68, 6-42. Two sequences share CDR3 (as indicated), some mutations (in blue), and switch point at position 41. Slashes indicate reference sequence not shown, portion deleted in cDNA clone.

D. 4-5, I3-8, I3-52, I3-96. I. The switch junction of 4-5 is shown, position 52 (arrow). II. The I3-series was obtained using first strand primer G5I4 at 1202 bp in the G5 J-C intron and PCR with G4L and G5I3 (at 1098 bp) to generate fragments of ~1498 bp. Three sequences shared CDR3 and switch point with 4-5. The duplication in I3-8 is marked.

E. 4-7. Switch point at position 60.

F. 4-70. Switch point marked by 1 bp deletion after position 48.

G. I7. Switch point at position 62, followed by large "deletion" and 3 bp insertion.

H. I16. Switch point at position 9, followed by "deletion" and 1 bp insertion before joining with G5 sequence.

I. I29. Switch point at position 36, followed by large "deletion. The 9 bp insertion is most likely a duplication of the adjacent GTCTGGGGT.

J. I36. Switch point at position 211, followed by large deletion. An alternative interpretation is the joining occurred through homology between G4A and G5 (underlined); the deletion and mutations would have occurred after switching.

K. I69. Switch point at position 30, "deletion" with 2 bp insertion.

L. Switch point at position 87, followed by large "deletion" and 5 bp insertion.

M. Switch point at position 76, followed by 9 bp insertion and extensive downstream changes.

N. I53. I. Switch point in G4A sequence is at position 311 but is taken up at position 169 in G5, generating a "duplication", as if unequal crossingover had taken place. II. The actual I53 sequence is aligned with the disparate regions of G4A and G5 to show insertion of 8 bp at the switch point before the sequence continues as G5.

O. I22. I. Switch point in G4A sequences is at position 195 but is taken up at position 28 in G5 generating a "duplication". II. I22 is aligned with the disparate regions of G4A and G5 to show insertion of 3 bp CGC before I22 continues as G5. P. I167.

P. I167. The switch junction of I167 includes 9 bp of sequence that is shared between G4A (86-95) and G5 (311-319) that may be involved in homology pairing.

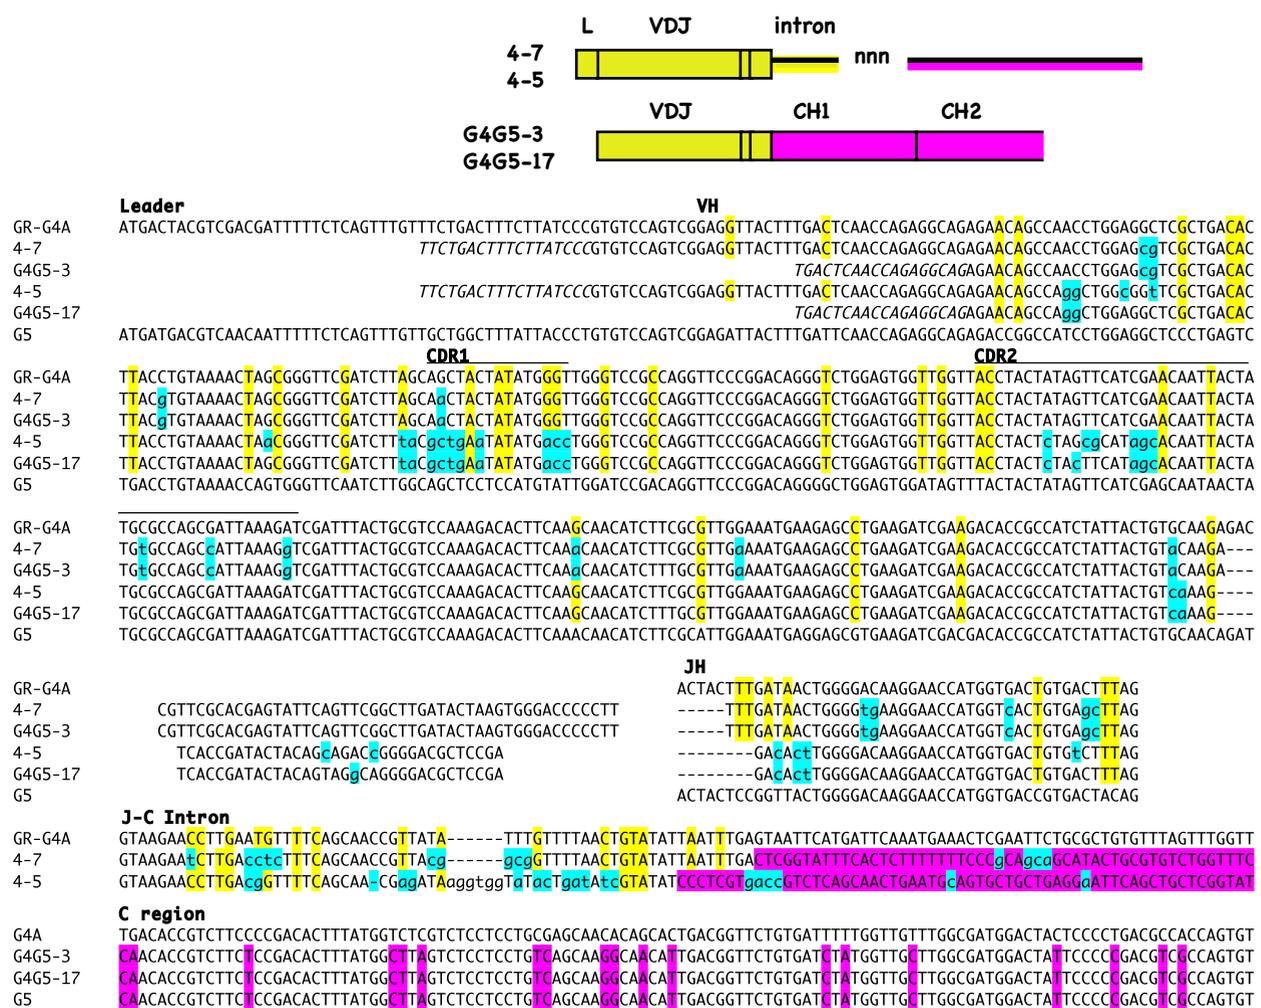

Fig. S5. Clonally related VDJ are flanked with switched intron or spliced to switched C region. Top, Diagram depicts the two kinds of sequences, VDJ flanked with intron (clones 4-7, 4-5) and VDJ spliced to C region (G4G5-3, -17). Yellow indicates G4 origin, pink G5. Bottom, Alignment of sequences with G4A and G5. Somatic mutations are highlighted in blue. See legend to Fig. 2.

Figure S6. A. IgW VDJ and IgM C region. Five cDNA sequences isolated from shark-GR epigonal library (Table 2) are compared with an IgW H chain cDNA (top, 105S; accession number AY609244) and IgM G2A H chain (bottom). Identities in VDJ highlighted in yellow, those in C region in pink; presumed mutations are in lower case and marked in blue. All cDNA were full-length and identical in C region sequence to the secreted form of G2A. Accession numbers JQ272792-96.

B. IgM VDJ and IgW C region. Clone c57 from shark-GR cDNA library is aligned with the IgM G4CG H chain sequence in the VH. Mutations are in lower case and highlighted in blue. Identities between G4CG and c57 JH highlighted in yellow. The C region of c57 (1961 bp, Accession number JN802117) is almost identical to that of clone 3 1-7 (AY524280), an IgW H chain sequence with a partial JH (as shown). The C region has been identified as belonging to the G5 subfamily of Ig ω genes (unpublished results). There are two gapping mismatches between 3 1-7 and c57 (shaded in 3 1-7), but the sequence of c57 has been confirmed and can be read through to its end. The C region is labeled CH1-4 according to the G4CG H chain sequence. The IgW sequences have two additional domains.
