MBIS – an integrated system for the retrieval and analyses of sequence data from nucleic acids, and proteins

C.A.Bucholtz and A.H.Reisner

CSIRO, Division of Molecular Biology, P.O. Box 184, North Ryde, NSW 2113 Australia

Received 2 July 1985

ABSTRACT

A computer-based system termed MBIS (the Molecular Biological Information Service), written in FORTRAN77 and Digital Command Language (DCL) and running on a Digital Equipment Corporation VAX computer under the VMS operating system (V4.1) is in use at the Division of Molecular Biology.

MBIS consists of three main sections: 1) The utility section, used by the system's manager to tailor the five commonly available databases so that they are useable by the applications programmes running on the system; 2) The retrieval section, used to find and extract specific sequences or bibliographic information, and 3) The analytical section, used to analyse and compare sequences either extracted from the databases or input by the user. The nucleotide databases maintained are GenBank, EMBL and PIR (Protein Identification Resource, National Biomedical Research Foundation) and the peptide databases are PIR and NEWAT. In addition, users can originate and maintain their own databases.

Those programmes which feature graphics output are compatible with most emulators of the Tektronix 4010 terminal.

INTRODUCTION

The retrieval and analysis of sequence data from nucleic acids and proteins are of major importance in molecular biology, and relatively easy to use integrated systems that assist research workers who are expert in molecular biology and biotechnology but not in the ways of computers have become necessities. The MBIS system (Molecular Biological Information Service) was placed on-line by the Division of Molecular Biology (DMB) in February 1985 [1] to meet the requirements of molecular biologists in

The source code and documentation for the MBIS system that have been developed at the DMB will be made available at approximately the cost of postage to non-commercial organizations who supply TWO 2400 ft 0.5 in. wide magnetic tapes; modified current versions of the GenBank, EMBL and NBRF databases under the conditions stipulated by each purveyor - will be included. We can only supply tape written at a density of 1600 bpi. Unless requested otherwise the tape will be written as a VAX "backup" tape. If the complete system is requested, permission must first be obtained from third parties who have allowed us to incorporate their applications software into MBIS. Their names and addresses will be supplied on request.

Nucleic Acids Research

Australia for information processing. It is accessible within Australia through CSIRO's CSIRONET network and can be accessed internationally through Tymnet. The system consists of just over one hundred programmes (about 100,000 lines of code), organized under a menu-driven tree structure which occupies, together with the databases, about 60 Mbytes. A running version (DCL programmes and executable binary images) together with the five databases occupies 25 Mbytes.

HARDWARE

MBIS runs on a Digital Equipment Corporation (DEC) VAX 11/750 Computer equipped with 3 Mbytes of memory, floating point accelerator, 456 Mbyte RA81 Winchester drive and TU80 industry standard tape drive (1600 bpi). Graphics are output to Tektronix 4010 or 4109 terminals and hardcopy is produced by a Tektronix 4695 ink jet printer.

SOFTWARE

Applications programmes developed at the DMB are written in either Digital Command Language (DCL), which runs under an interpreter or DEC's implementation of FORTRAN77; where appropriate, use is made of the runtime library. Currently, about half of the software running on the system has been developed at the DMB. The rest of the programmes has been contributed principally by Staden [2-8], and Kanehisa [9]. Additional programmes which are in use on the system have been donated by Novotny [10] and Novitski and Neri (Nagley, personal communication). In order to make the system appear unified to the user and to allow a common record structure for sequence data, virtually all of the programmes (with the exception of those of Staden which do not yield graphics output) required rewriting.

THE MOLECULAR BIOLOGICAL INFORMATION SERVICE (MBIS)

A user of MBIS, once he has had his password accepted, is confronted by the following output on his terminal. (Note: if there is ambiguity below, text commentary is enclosed in $\{\}$):

> CSIRO, Division of Molecular Biology's Molecular Biological Information Service - (MBIS) (for NOTICES type NO)

{If the system's manager has made him a captive user with a special login file the following menu appears: }

Help level full=1 prompt=2 none=3 or <CR>

{In what appears below user input is shown underlined: }
Enter level required: 1

{A novice user would be expected to type "1" and get the full menu shown below while one with more experience by typing "2" would see only a prompt line containing just the two letter commands.}

(AN,AU,C,CA,CD,DB,E,M,S,SA,T,DIR,MENU,HELP,X) Enter code:

Most of the options listed above are self explanatory, however, a few comments may be warranted. The C or CA commands (compare or compAll) make use of the quasi correlation coefficient (Qr) [11,12] to allow high speed searching of the nucleotide databases or the correlation coefficient (r) [13]for searching the amino-acid-residue databases. These options make use of secondary databases which are created whenever a new primary one is received. The option M (match) on the other hand is an implementation of the algorithm developed by Wilber and Lipman [14] and the software used is based on FORTRAN code written by Kanehisa et al., [9].

A separate "directory", made up of several lines of descriptive information about each sequence entry, is created for every database and cross-indexed to them. The "S" and "SA" options are used to search these directories, and Boolean operators may be used. The utility is based on a programme supplied by the PIR. An example of its use for the NEWAT database is given below:

(AN, AU, C, CA, CD, DB, DIR, E, M, S, SA, T, MENU, HELP, X) Enter code:s

TYPE OS TO HALT THE SCREEN, OQ TO RESTART, AND OY TO ABORT © = Control key Enter string (U or L case) - sheep or " ovine" You have typed - sheep or " ovine" Is this correct (Y/N)? y Do you want to print (P), view (V) or file (F) the searches (P/V/F)? v Searching the NEWAT data base directory Title Start CRFX CORTICOTROPIN RELEASING FACTOR PRECURSOR, SHEEP 4633 ٠ RHOV RHODOPSIN, OVINE (C-TERM FRAG) 6293 •

(AN,AU,C,CA,CD,DB,DIR,E,M,S,SA,T,MENU,HELP,X) Enter code: t

The option T (type) allows the user to have information output to his terminal, to a file in his disc area or to the VAX's line printer. In addition, he may chose to have output just the bibliographic information available for a given entry or <u>that</u> information together with the sequence itself. The sequence, however, is not output in a computer readable form but rather in one easy to read by individuals. The response to having typed "t" is shown below: Do you want to Print (P), view (V) or file (F) the output (P/V/F)?: v TYPE OS TO HALT THE SCREEN, OQ TO RESTART, AND OY TO ABORT THIS PROGRAMME LISTS OUT SECTIONS OF THE NEWAT PROTEIN DATA BASE Whole entry printed (information + sequence) (W) or just the information (I): (W/I) w Enter record start position (Enter -1 to finish) : 6293 Enter record start position (Enter -1 to finish) : -1RHODOPSIN, OVINE (C-TERM FRAG) RHOV Findlay et al (1981) Nature, 293, 314. 9 Ile I

Number of residues = 109

8 Val V

The E (extract) option creates the 60 character records used by the analysis programmes. Only the sequence is transcribed into a file designated by the user.

6 Pro P

The CD (CreateDB) option allows the user to create databases of his own in his disc area. They are written as EMBL formatted entries, are accessible only by the individual creating them, unless he specifically requests the system manager to make them public, and he may create as many different ones as he has space for.

DISCUSSION

In designing MBIS we have not tried to reconfigure the five databases to a common single format which would tend to restrict the use of some of the features present in one or another of them. In addition when changes in format for a given database occur, it is relatively simple to alter those parts of the utility section which have to be modified. GenBank is a special case in that between full quarterly issues of the database, monthly updates are supplied which are used to replace entries which have been found to be in error as well as adding new entries. The MBIS software contains the utilities to perform the "interleaving".

To the user the system appears unified, i.e. he is shielded from the changes required to deal with the different databases, and this reduces the number of commands that are needed to drive the system. Finally, the use of the DCL shell allows the amalgamation and ready addition of software without altering the apparent fabric of the system.

ACKNOWLEDGEMENTS

We thank those individuals and groups who have sent copies of source code to us; in particular R. Staden, M. Kanehisa, R.F. Doolittle, J.Novotny, the Protein Identification Resource and P. Nagley.
