Whole blood cells stimulated with PMA/ionomycin were fixed with 4% paraformaldehyde after lysing the RBCs, and cryopreserved until used. At the time of analysis the cells were thawed and stained with all antibodies in the cocktail (Table S1) except the one that registers in the channel of particular interest [Fluorescence Minus one (FMO) Staining]. The gate drawn for each channel was used to determine the frequency cytokine producing cells in response to antigen stimulation in that channel.

## Flow Cytometry

Cryopreserved fixed whole blood cells were thawed at room temperature and washed twice with 1X PBS and transferred to 96-wells V-bottom costar plates (Corning). The cells were then incubated with 1X Permeabilization buffer (eBioscience) for 15 minutes at room temperature and washed again with 1X Permeabilization buffer. The cells were then blocked for 15 minutes at room temperature then washed again with 1X Permeabilization buffer. The cells were then incubated with antibodies for the effector and regulatory panels for 30 minutes then washed twice with PBS. After washing, the cells were resuspended in 0.2 ml of PBS and transferred to 96-plug micro tubes (Bio-Rad) and acquired on an LSRII (BD Bioscience).
