General Materials and Methods

All reactions were performed under a dry argon atmosphere, unless otherwise stated. All solvents and reagents were obtained from commercial sources and used without further purification unless otherwise stated. *N*-Boc-*O*-Benzyl-protected siderophore **S1** was synthesized as described previously by Roosenberg and Miller.¹ Dichloromethane (CH_2Cl_2) was distilled from calcium hydride. Tetrahydrofuran (THF) was distilled from Na/benzophenone. Dimethylformamide (DMF), diisopropylethylamine ($i\text{Pr}_2\text{EtN}$), and acetonitrile (CH_3CN) were used from Acros Seal anhydrous bottles. Silica gel column chromatography was performed using Sorbent Technologies silica gel 60 (32-63 μm). $^1\text{H-NMR}$ and $^{13}\text{C-NMR}$ spectra were obtained on a 300 MHz, 500 MHz, or 600 MHz Varian DirectDrive spectrometer and FIDs were processed using ACD/ChemSketch version 10.04. Chemical shifts (δ) are given in parts per million (ppm) and are referenced to non-deuterated residual solvent. Coupling constants (J) are reported in hertz (Hz). High resolution, accurate mass measurements were obtained on a Finnigan MAT 8430 spectrometer using fast atom bombardment (FAB) ionization or with a Bruker micrOTOF II electrospray ionization time-of-flight mass spectrometer in positive ion mode. Sample was introduced via flow injection at a rate of 4 $\mu\text{L}/\text{min}$, and mass spectra were accumulated from 50-3000 m/z for two minutes. Crystallographic data were collected at Beamline 11.3.1 at the Advanced Light Source (ALS), Lawrence Berkeley National Laboratory. Analytical high-performance liquid chromatography (HPLC) was performed on a Waters 1525 Binary HPLC Pump instrument with a Waters 2487 Dual λ Absorbance Detector set at 427 nm operated by Breeze version 3.30 software. HPLC-MS was performed on a Waters ZQ instrument consisting of a chromatography module Alliance HT, photodiode array detector 2996, and mass spectrometer Micromass ZQ with an MS electrospray source operate at capillary voltage 3.5 kV and a desolvation temperature of 300 °C. Both HPLC and HPLC-MS instruments used a YMC Pro C18 reverse phase column (3.0 x 50 mm) fit with precolumn frit (0.5 μm) and YMC Pro C18 guard column (2.0 x 10 mm) for all analyses. Mobile phases used were 10 mM ammonium acetate in HPLC grade water (A) and HPLC grade acetonitrile (B). A gradient was formed from 5%–80% of B in 10 min, then 80%–95% of B in 2 min, and then 95%–5% of B in 3 min at a flow rate of 0.7 mL/min (total run time of 15 min). Semi-preparative HPLC purifications were performed on a Waters semi-preparative binary pump system at a flow rate of 15 mL/min with detection by UV detection at 427 nm with separation facilitated by a YMC-Pack Pro C18 column, 150 x 20 mm (I.D.), particle size 5 μm fit with a guard column. Thin layer chromatography (TLC) was performed with aluminum-backed Merck 60-F₂₅₄ silica gel plates or aluminum-backed Merck RP-C18 F₂₅₆ silica gel plates plates using a 254 nm lamp or aq. FeCl_3 for visualization. Melting points were determined in capillary tubes using a Thomas Hoover melting point apparatus and are uncorrected.

General Procedure A: Hydrogenolysis of benzyl protected siderophores.

Fully benzyl protected siderophore (**S3**, **S4a-S6a**, **S7**, **S9**, **S11**) was dissolved in MeOH (~0.01 M) in an HCl-washed, oven-dried round bottom flask fitted with a magnetic stir bar. The flask was flushed with argon, charged with 10% Pd-C (~10% w/w), and flushed with H_2 gas (balloon) several times using intermediate vacuum evacuations. The mixture was then left stirring under an H_2 atmosphere (~1 atm; balloon) and periodically monitored by RP-C18 TLC (1.5:1 $\text{CH}_3\text{CN}:\text{H}_2\text{O}$; FeCl_3 Stain). Once complete, the mixture was flushed with argon, vacuum

filtered through celite, and concentrated under reduced pressure. The crude product was dissolved in a minimal amount of MeOH and precipitated by addition of Et₂O. The siderophore (**3**, **S4b-S6b**, **S8**, **S10**, **S12**, **S13**) was isolated as a white or off-white solid after trituration with Et₂O and drying under vacuum.

General Procedure B: Complexation of siderophores to Fe(III).

The siderophore (**3**, **S4b-S6b**, **S8**, **S10**, **S12**, **S13**) was dissolved or suspended in MeOH (0.002 M) and the solution was heated to 40 °C (oil bath temp.). Fe(acac)₃ (1.1 equiv) was added and the clear, orange solution was stirred for 2 h. The MeOH was removed under reduced pressure giving the siderophore-Fe(III) complex as an orange film. The complex was then dissolved in a minimal amount of MeOH and precipitated by addition of Et₂O. The siderophore-Fe(III) complex (**5a,c-8a,c**) was isolated as an orange powder after trituration with Et₂O and drying under vacuum.

Hydroxylamine S2. The *N*-Boc protecting group of compound **S1** (5.01 g, 0.0051 mol) was removed by treatment with anhydrous TFA in CH₂Cl₂ followed by free basing with sat. aq. NaHCO₃ to give the corresponding hydroxylamine (**S2**) in 99% yield as an amorphous solid (4.49 g, 0.0051 mol). ¹H-NMR (500 MHz, CDCl₃) δ 7.40–7.26 (m, 20 H), 6.33 (br s, 2 H) 4.85 (s, 2 H), 4.84 (s, 2 H), 4.70 (s, 2 H), 4.47 (s, 2 H), 3.69–3.56 (m, 4 H), 3.44 (t, *J* = 6.6 Hz, 2 H), 3.21 (t, *J* = 6.3 Hz, 2 H), 3.17 (t, *J* = 6.0 Hz, 2 H), 2.91 (t, *J* = 7.2 Hz, 2 H), 2.86–2.74 (m, 4 H), 2.52–2.44 (m, 4 H), 1.70–1.22 (m, 18 H).

After 26.5 h at rt, TLC (9% MeOH in DCM; FeCl₃ stain) showed no remaining hydroxylamine (**S2**). The mixture was diluted with CH₂Cl₂ (50 mL) and 1 N HCl (35 mL) was added, respectively. The organic layer was separated and washed with brine (35 mL), dried over anhydrous MgSO₄, filtered through celite, and concentrated under reduced pressure. The crude product was purified by silica gel column chromatography (5%-9.5% MeOH in CH₂Cl₂ as eluent) to give the desired product (**S3**) in 98% yield as a white solid (recrystallized from hexanes/EtOAc at -20 °C; 4.90 g, 0.005 mol). Mp 114–118 °C (dec.); HRMS-ESI (m/z): [M+H]⁺ calcd. for C₃₀H₅₃FeN₅O₁₁: 715.3086, found 715.3114; HPLC retention time 3.92 min.

Desferridanoxamine macrolactone (4). Danoxamine macrolactone **5b** (9.5 mg, 0.0145 mmol) was dissolved in 5 mL of 0.53 M aq. Na-EDTA (2.65 mmol Na-EDTA). After 15 h, the solution had turned from clear orange to clear and colorless. The desferrisiderophore was extracted into a 1:1 phenol:CHCl₃ mixture (2 x 30 mL). The phenol:CHCl₃ was then diluted with Et₂O (360 mL) and the desferrisiderophore was extracted back into H₂O (3 x 100 mL). The H₂O was evaporated using high vacuum rotary evaporation to give the pure desferridanoxamine macrolactone **4** in 95% yield as a clear, colorless film (8.3 mg, 0.014 mmol). ^1H -NMR (500 MHz, CD₃OD) δ 4.08 (t, J = 6.1 Hz, 2 H), 3.61 (t, J = 6.3 Hz, 6 H), 3.17 (t, J = 6.2 Hz, 4 H), 2.78 (t, J = 6.3 Hz, 6 H), 2.57 (t, J = 6.5 Hz, 2 H), 2.47 (t, J = 6.8 Hz, 4 H), 1.71–1.57 (m, 8 H), 1.56–1.47 (m, 4 H), 1.43–1.26 (m, 6 H); ^{13}C -NMR (125 MHz, CD₃OD) δ 175.1, 174.9, 174.6, 174.6, 174.4, 65.7, 49.4, 48.9, 48.7, 40.3, 40.2, 31.8, 31.7, 30.0, 29.9, 29.8, 29.5, 29.2, 29.1, 28.6, 27.4, 27.3, 27.3, 24.8, 24.6, 24.1; HRMS-ESI (m/z): [M+H]⁺ calcd. for C₂₇H₄₈N₅O₁₀: 602.3396, found 602.3393.

(±) Danoxamine macrolactone (5b). Danoxamine (**5a**; 75.0 mg, 0.11 mmol), 2,4,6-trichlorobenzoyl chloride (51.6 μ L, 0.33 mmol), iPr₂EtN (115.0 μ L, 0.66 mmol), and catalytic DMAP (6.8 mg, 0.056 mmol) were dissolved in 23 mL of anhydrous DMF (0.005 M with respect to **5a**). After 144 h, HPLC (visible detection at 427 nm) showed the desired macrolactone to be the major siderophore-containing reaction component. The reaction was

quenched with H₂O (10 mL) and the DMF/H₂O were removed using high vacuum rotary evaporation. The resulting orange film was partitioned between H₂O (75 mL) and Et₂O (50 mL). The layers were separated and the H₂O was washed with Et₂O (2 x 50 mL) and concentrated to give 72 mg of an orange film. This material was purified by semi-preparative HPLC using 0.1 mM ammonium acetate H₂O (A) and CH₃CN (B) as eluent. A gradient was formed from 95%-20% of A in 10 min, then 20%-5% of A in 2 min, then 5%-95% of A in 3 min (total run time = 15 min). Pure fractions were concentrated to provided danoxamine macrolactone **5b** in 53% yield (39.0 mg, 0.060 mmol). X-ray quality crystals were grown from MeOH/Et₂O at -20 °C. An X-ray structure was obtained by Dr. Allen Oliver (UND) at the Advanced Light Source Beamline at Lawrence Berkeley National Lab as described in section **XII** of this Supporting Information. HRMS-ESI (m/z): [M+Na]⁺ calcd. for C₂₇H₄₄FeN₅NaO₁₀: 677.2330, found 677.2373; HPLC retention time 3.67 min.

Optimization of Yamaguchi conditions for the macrolactonization of danoxamine (Table 1; Entries 1-4). All reactions were performed in anhydrous DMF using 5 mg of danoxamine (**5a**) at a concentration of 0.005 M and 0.5 equivalent of DMAP. Varying amounts of the Yamaguchi reagent (2,4,6-trichlorobenzoyl chloride) and iPr₂EtN were included along with varying reaction temperatures, as indicated in Table 1, Entries 1-4. Relative percent compositions were determined after 72 h by quenching the reaction mixture with MeOH. The quenched mixture was analyzed by HPLC and/or LC-MS with visible detection at 427 nm, the λ_{max} for 1:1 trihydroxamate siderophore:Fe(III) complexes, to identify and quantify all reaction components (**5a-5e**) as shown in Table 1.

Scope of Yamaguchi macrolactonization conditions. Syntheses of ferric siderophore macrolactones **5b-8b (Table 1; Entries 5-8).** All reactions were performed in anhydrous DMF using 1 mg of siderophore-Fe(III) hydroxy acid (**5a-8a**) at a concentration of 0.005 M with 3.0 equivalents of 2,4,6-trichlorobenzoyl chloride, 6.0 equivalents of iPr₂EtN, and 0.5 equivalent of DMAP added from stock solutions. Relative percent compositions were determined after 72 h by quenching the reaction mixture with MeOH and analyzing by HPLC with visible detection at 427 nm, the λ_{max} for 1:1 trihydroxamate siderophore:Fe(III) complexes. Some reaction mixtures were heated to 50 °C to ensure complete solubilization of the siderophore, as indicated in Table 1. The identity of the siderophore macrolactones (**5b-8b**) was confirmed by HRMS, LC-MS, and analytical HPLC. **6b, n=1.** HRMS-ESI (m/z): [M+H]⁺ calcd. for C₂₆H₄₃FeN₅O₁₀: 641.2354, found 641.2326; HPLC retention time 3.37 min. **5b, n=2.** HRMS-ESI (m/z): [M+Na]⁺ calcd. for C₂₇H₄₄FeN₅NaO₁₀: 677.2330, found 677.2373; HPLC retention time 3.67 min. **7b, n=3.** HRMS-ESI (m/z): [M+H]⁺ calcd. for C₂₈H₄₇FeN₅O₁₀: 669.2667, found 669.2657; HPLC retention time 3.20 min. **8b, n=4.** HRMS-ESI (m/z): [M+H]⁺ calcd. for C₂₉H₄₉FeN₅O₁₀: 683.2823, found 683.2781; HPLC retention time 4.00 min.

Hydrolysis of siderophore-Fe(III) complex methyl esters (5c-8c**) to acids (**5a-8a**).** All reactions were performed in H₂O buffered to pH 10 (K₂CO₃, K₃BO₃, KOH; Fisher) at 22 °C with a siderophore-Fe(III) complex methyl ester (**5c-8c**) concentration of 0.5 mM. Reaction half-lives (t_{1/2}) and R² values were derived from linear first order kinetic plots (ln[siderophore-Fe(III) methyl ester] versus time) generated by integrating the siderophore ester and acid peak areas of HPLC chromatograms collected at various time points with visible detection at 427 nm, the λ_{max} for 1:1 trihydroxamate siderophore:Fe(III) complexes.

^aAll data values in this table were generated from HPLC chromatograms of macrolactonization reaction mixtures described in Table 1 of the main text. ^bTime points refer to the exact time of quenching the reaction mixture with MeOH. ^cHeight refers to the peak height of the reaction components when monitored at 427 nm ^dRelative percent compositions were determined for all siderophore components using the peak heights at 427 nm, which is the wavelength of max absorbance for trihydroxamate siderophore-Fe(III) complexes.

XII. X-ray Diffraction Data for **5b**

Discussion

The complex **5b** crystallizes as red, blade-like crystals. There are two molecules of the complex, a racemic mixture of Λ/Δ -cis coordination isomers, and associated water molecules of crystallization in the unit cell of the primitive, centrosymmetric, triclinic space group P-1.

The structure of the complex is as expected (see Figure 3 in main text). The iron adopts an octahedral coordination geometry and is coordinated by six oxygens of the siderophore macrocycle. Though the data resolution was not as high as often desired, location of the hydrogens on the macrocycle and water molecules was possible. This allowed identification of the lactone oxygen since the amide hydrogens were observed. The amides and water molecule all form hydrogen bonds to nearby H-bond acceptor atoms (see Table S8 of Hydrogen-bonds for details). The molecules form 2D H-bonded sheets within the lattice. The H-bond from N3 to the neighboring oxime oxygen, O1, propagates chains along the *a*-axis. The H-bond from N5 to the carbonyl O7 of a molecule related by translation along the *b*-axis, propagates the sheet along that axis. The water molecule forms a bifurcated hydrogen-bond to the carbonyl oxygens O2 and O9 (which also coordinate the Fe center) and an H-bond to the same carbonyl, O7, contacted by N5.

The data quality is not as high as usually desired, however, the connectivity and identity of the molecules are unequivocal. The bond distances and angles are within reasonable, expected values, though they do have somewhat larger than normal standard uncertainties.

Limited examples of ferrioxamine siderophore x-ray structures have been solved and presented in the literature. These structures include ferrioxamine B,²⁻³ ferrioxamine D₁,⁴ ferrioxamine E,⁵ and a retro-hydroxamate isomeric structure of ferrioxamine E.⁶ A comparative analysis of these structures has been reported and the structural parameters of danoxamine macrolactone presented here are in good agreement.²

The propeller-like structures and conformational features of danoxamine macrolactone (**5b**) and ferrioxamine E, both macrocyclic ferrioxamine siderophores with a preformed cavity for binding Fe(III),^{2,5} compare very well with each other as shown in figure S22 A and B, respectively. One interesting structural difference is observed when viewing space filling models of the two faces of the siderophore structures. Both structures present three carbonyl groups on one face, but on the opposing face ferrioxamine E presents three amide NH groups (H-bond donors) while danoxamine macrolactone presents two amide NH groups (H-bond donors) and one ester oxygen (H-Bond acceptor). This subtle structural difference could influence biological activity of the siderophores since recognition and transport by membrane-associated siderophore receptor/transport proteins is highly dependent on the presented structural features surrounding the Fe(III)-octahedron of the siderophore.²

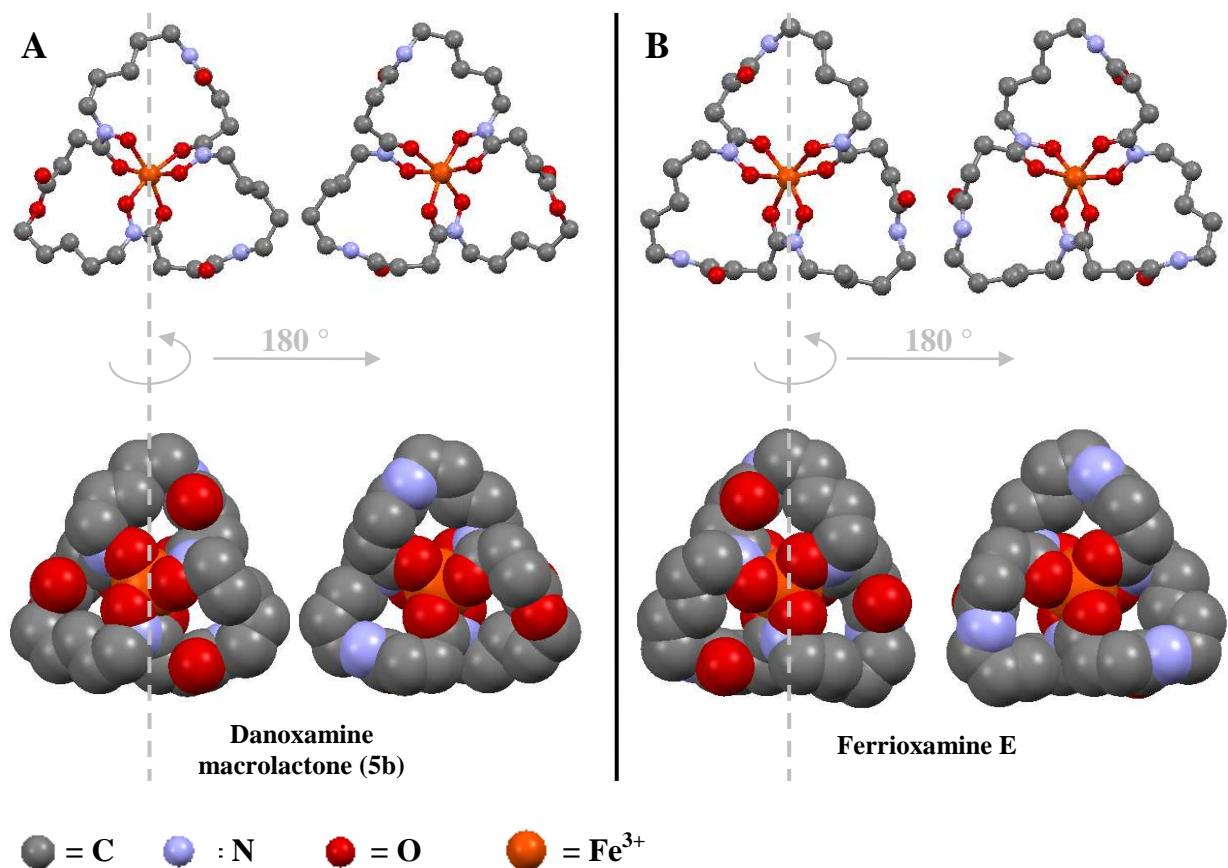

Figure S22. Comparison of danoxamine macrolactone (**5b**; **A**) and ferrioxamine E (**B**) X-ray structures viewed through the pseudo C_3 axis using ball and stick and space filling models generated by Mercury version 2.4 (cif file for ferrioxamine E (FEROXE10)⁵ was obtained from the Cambridge Structural Database).

Residual electron density ($e^- \cdot \text{\AA}^{-3}$) max/min: 0.884/-0.896.

An arbitrary sphere of data were collected on a red blade-like crystal, having approximate dimensions of $0.06 \times 0.05 \times 0.015$ mm, on a Bruker APEX-II diffractometer using a combination of ω - and φ -scans of 0.3° .⁷ Data were corrected for absorption and polarization effects and analyzed for space group determination. The structure was solved by direct methods and expanded routinely. The model was refined by full-matrix least-squares analysis of F^2 against all reflections. All non-hydrogen atoms were refined with anisotropic thermal displacement parameters. Unless otherwise noted, hydrogen atoms were included in calculated positions. Thermal parameters for the hydrogens were tied to the isotropic thermal parameter of the atom to which they are bonded (1.5 × for methyl, 1.2 × for all others).⁸⁻¹⁰

We thank UND Lizzadro Magnetic Resonance Research Center for NMR facilities and MS services by UND Mass Spectrometry & Proteomics Facility (Mrs. N. Sevova, Dr. W. Boggess, and Dr. M. V. Joyce; NSF, CHE-0741793). Samples for synchrotron crystallographic analysis were submitted through the SCrALS (Service Crystallography at Advanced Light Source) program. Crystallographic data were collected at Beamline 11.3.1 at the Advanced Light Source (ALS), Lawrence Berkeley National Laboratory. The ALS is supported by the U.S. Dept. of Energy, Office of Energy Sciences, under contract DE-AC02-05CH11231.
