^a Pre- and postnatal BPA urinary concentrations were SG-adjusted and dichotomized as Q4 vs. Q1-Q3 based on logarithm transformed SG adjusted values

^b Adjusted for postnatal BPA measurements, prenatal mono-n-butyl phthalate concentration, age at assessment, smoking at home, child sex, maternal education (≥high school or not), ethnicity (African American or not), gestational age, HOME inventory, TONI score, and maternal demoralization during pregnancy.

^cThe seven Syndromes scales were fitted using Poisson log-linear models. For interpretability we report the exponentiated beta in the Estimate column. The two Composite scales were fitted in linear models. Therefore, in that Estimate column, the values are the original betas. In addition, the estimates for the Syndrome scores indicate multiplicative difference between high and low exposure, whereas the estimate for composite scores indicates the average difference in scores for high versus low exposure on an absolute scale

^a Pre- and postnatal BPA concentrations were dichotomized as upper quartile based on logarithm transformed SG-adjusted values

^b Four types of models were fitted separately to assess the main effects of prenatal BPA on both boys and girls (column 1), boys only (column 2) and girls only (column 3) and the interaction effects of prenatal BPA on both boys and girls (column 4).

^c The covariates in each model are the same: postnatal BPA measurements, prenatal mono-n-butyl phthalate concentration, age at assessment (in months), smoking at home (yes or no), child sex, maternal education (≥high school or not), ethnicity (African American or not), gestational age (in weeks), HOME inventory score, TONI score, and PERI-D score.

^d The seven Syndromes scales were fitted using Poisson log-linear models. For interpretability we report the exponentiated beta in the Estimate column. The two Composite scales were fitted in linear models. Therefore, in that Estimate column, the values are the original betas. In addition, the estimates for the Syndrome scores indicate multiplicative difference between high

and low exposure, whereas the estimate for composite scores indicates the average difference in scores for high versus low exposure on an absolute scale
