

Additional File 1 Model reconstruction

The metabolic reactions of the metabolic model of *Bacillus subtilis* for isobutanol production were derived from the recently published genome-scale metabolic network [1, 2]. The metabolic network of isobutanol-producing *B. subtilis* used for metabolic pathway analysis was constructed as follows. (i) Isobutanol biosynthetic reaction (R130) was introduced in the *B. subtilis* stoichiometric model to covert α -ketoisovalerate into isobutanol. (ii) The original genome-scale metabolic network was refined to take glucose as the primary substrate via phosphotransferase system (PTS). (iii) For ATP production in the respiratory chain a P/O ratio of 1.33 (for NADH) and 0.89 (for FADH₂) was assumed [3]. (iv) The biomass composition and cell molecular (Mr=25.03 g/mol, D=0.1 h⁻¹) were taken from Dauner and Sauer [4]. (v) Except for the central carbon metabolism, the linear reactions involved in other metabolic subsystems were lumped when necessary. (vi) It is assumed that water, protons and phosphate are ubiquitous in the cells and not limiting.

Table S1 Stoichiometric equations of the metabolic model of isobutanol-producing *B. subtilis* BSUL03

In the reaction equations, GDP, CMP, UDP and UMP were omitted for simplicity [5]. Except for biomass with the unit of “mg”, other units of stoichiometric coefficient are in “mol”. Symbol ‘-->’ indicates irreversible reactions, ‘<==>’ indicates reversible reactions.
