Additional file 1.pdf

Simple and brief survey of the literature for articles that presented bone-related RT-qPCR data in 2011-2012.

Aim

We wished to determine how prevalent the use of validated reference genes was in current bone-related RT-qPCR studies, and also whether single or multiple reference genes were used.

Method

Using the PubMed search engine, we limited the searches to the year 2011-2012 (year to date) and to articles that were open access and in English. The search was refined by using search terms:

Search A: osteogenesis AND gene AND expression AND PCR AND real-time

Search B: gene expression OR RT-PCR OR quantitative PCR - limited to the journal "Bone"

The two different searches were carried out to survey trends in bone-related literature in journals in general and in literature from a bone specific journal. We manually identified the reference gene/s used for normalization and noted if evidence of validation had been presented. This was done for the 15 most recent articles as defined by each search pattern and the findings are presented in table form.

Results

Presented in Tables 1 and 2 on the following pages.

Conclusions

1. 93% (23/30) of RT-qPCR studies surveyed used single, non-validated genes to normalize data.
2. The classical housekeeping gene *GAPDH* was the most commonly used (57%), followed by *18S rRNA* (13%) and *ACTB* (13%).

Bone to pick: the importance of evaluating reference genes for RT-qPCR quantification of gene expression in craniosynostosis and bone-related tissues and cells
