## Phosphometabolite Equations

During pre-ischemia, all metabolites are held at their initial values. During ischemia:

$$[\text{ATP}] = 0.0006549t^3 - 0.02305t^2 - 0.104837t + 7.216 \tag{S.1}$$

$$[\text{PCr}] = -0.01259 + 12.339e^{-0.92559t} + 0.96819e^{-0.078496t} \tag{S.2}$$

During reperfusion:

$$[\text{ATP}]_t = [\text{ATP}]_{t\text{-}\Delta t} - \frac{[\text{ATP}]_{t\text{-}\Delta t} - 0.4[\text{ATP}_{\text{preischemic}}]}{5\text{x}10^3\text{ms}}\Delta t \tag{S.3}$$

$$[\text{PCr}]_t = [\text{PCr}]_{t\text{-}\Delta t} - \frac{[\text{PCr}]_{t\text{-}\Delta t} - 0.75[\text{ion}_{\text{preischemic}}]}{5\text{x}10^3\text{ms}}\Delta t \tag{S.4}$$

During ischemia and reperfusion:

$$[\text{Cr}] = 22.2 - [\text{PCr}] \tag{S.5}$$

$$[\text{ADP}] = \frac{[\text{ATP}] * [\text{Cr}]}{[\text{PCr}] * [\text{H}_i^+] * 1.66\text{x}10^6} \tag{S.6}$$

$$[\text{AMP}] = \frac{[\text{ADP}] * [\text{ADP}] * 1.05}{[\text{ATP}]} \tag{S.7}$$

$$[\text{Pi}_{\text{free}}] = [\text{Pi}_{\text{total}} - (3 * [\text{ATP}] + 2 * [\text{ATP}] + [\text{AMP}] + [\text{PCr}]) \tag{S.8}$$
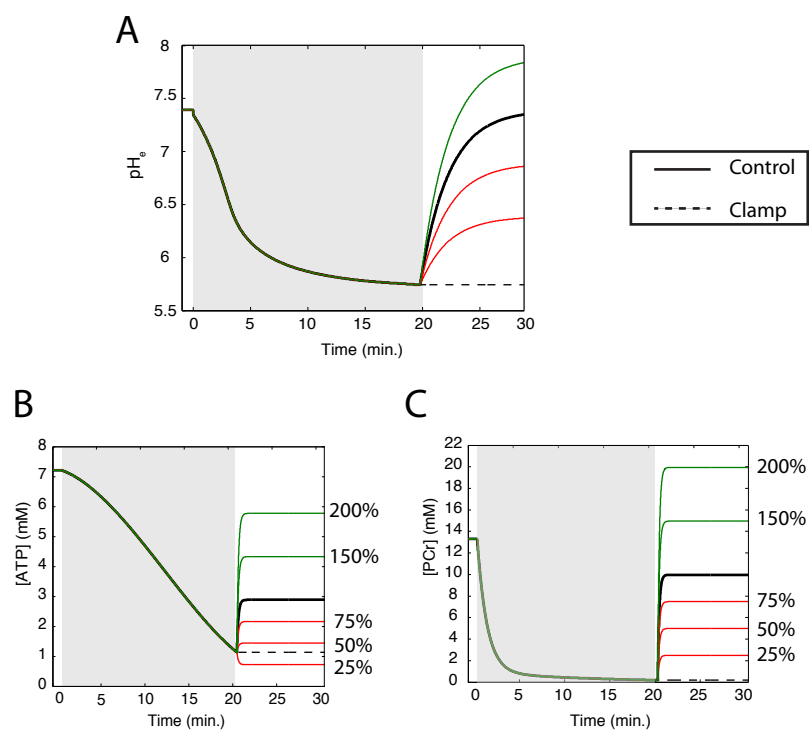

Figure S1: **Summary of simulations.** In each simulation, the end-reperfusion targets of extra-cellular pH ($pH_e$) (A) and/or ATP (B) and PCr (C) were controlled. Gray regions denote ischemic phase of simulations. See text for additional information.
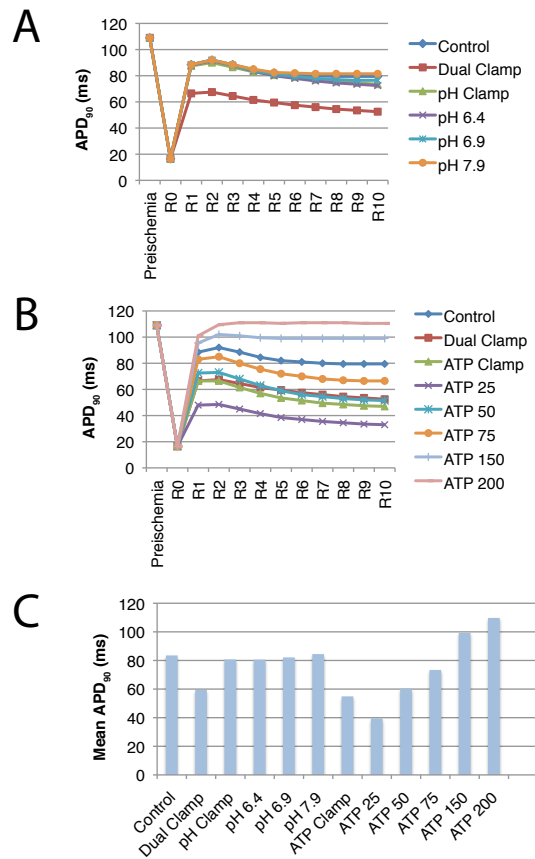

Figure S2: **Action potential duration (90) during simulated reperfusion.** The evolution of action potential duration (90) ($APD_{90}$) throughout reperfusion is shown for the series of simulations examining the effects of varying $pH_e$ (A) and phosphometabolite concentrations (B). Values recorded at the end of preischemia, at the beginning of reperfusion (R0), and once per minute of reperfusion (R1-R10) are shown. The mean $APD_{90}$ during reperfusion for each simulation is shown in (C).
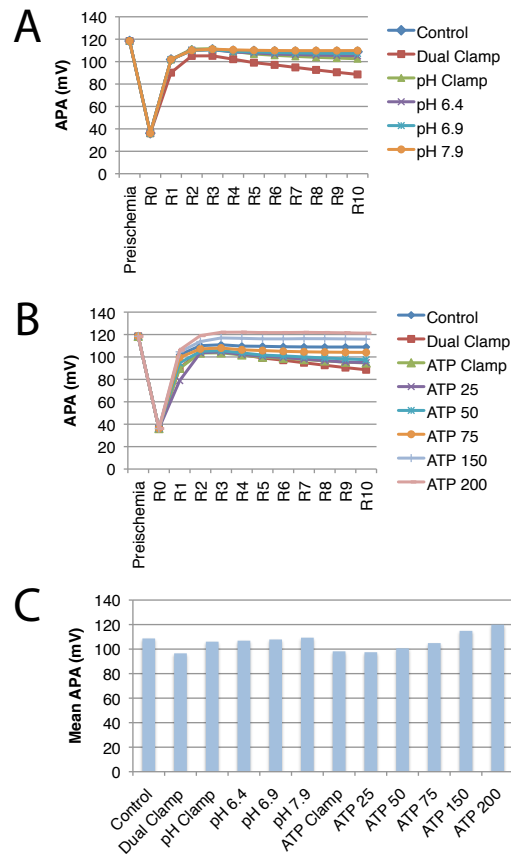

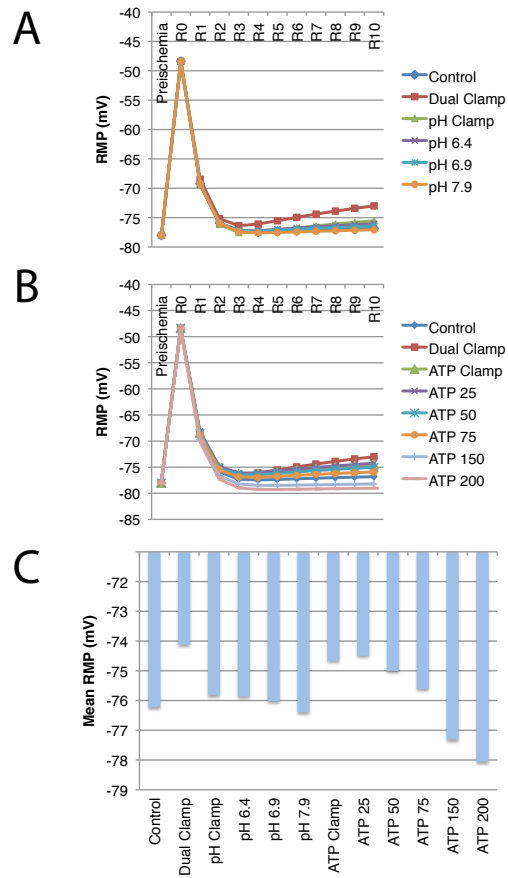

Figure S3: **Action potential amplitude during simulated reperfusion.** The evolution of action potential amplitude (APA) throughout reperfusion is shown for the series of simulations examining the effects of varying $pH_e$ (A) and phosphometabolite concentrations (B). Values recorded at the end of preischemia, at the beginning of reperfusion (R0), and once per minute of reperfusion (R1-R10) are shown. The mean APA during reperfusion for each simulation is shown in (C).

Figure S4: **Resting membrane potential during simulated reperfusion.** The evolution of resting membrane potential (RMP) throughout reperfusion is shown for the series of simulations examining the effects of varying $pH_e$ (A) and phosphometabolite concentrations (B). Values recorded at the end of preischemia, at the beginning of reperfusion (R0), and once per minute of reperfusion (R1-R10) are shown. The mean RMP during reperfusion for each simulation is shown in (C).
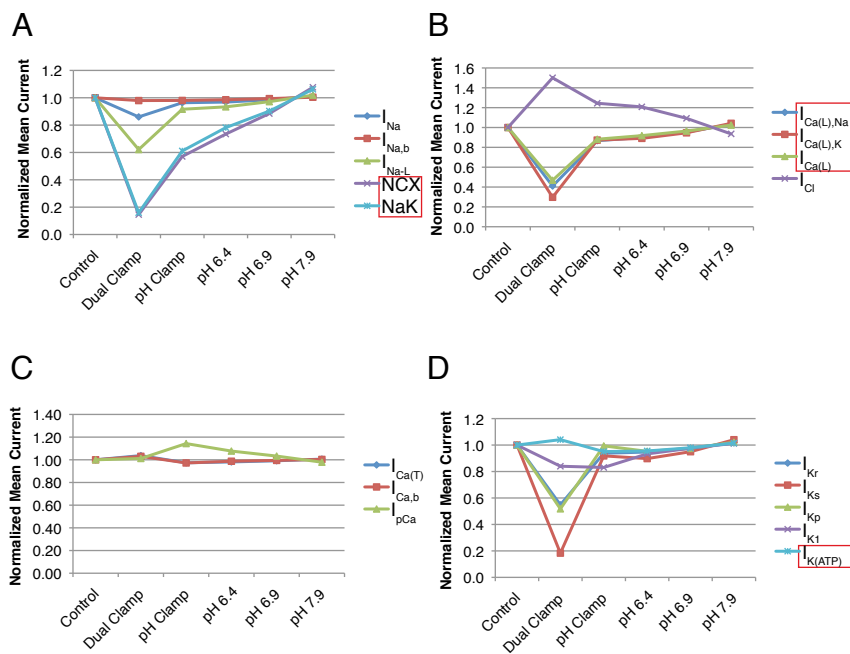

Figure S5: **Normalized mean currents throughout 10 minutes of reperfusion with variable** pH$_e$ **recovery.** For each of 17 transmembrane currents, mean current in each simulation is normalized to the corresponding control. Currents that are directly modulated by pH and/or phosphometabolite concentrations are shown in red boxes.
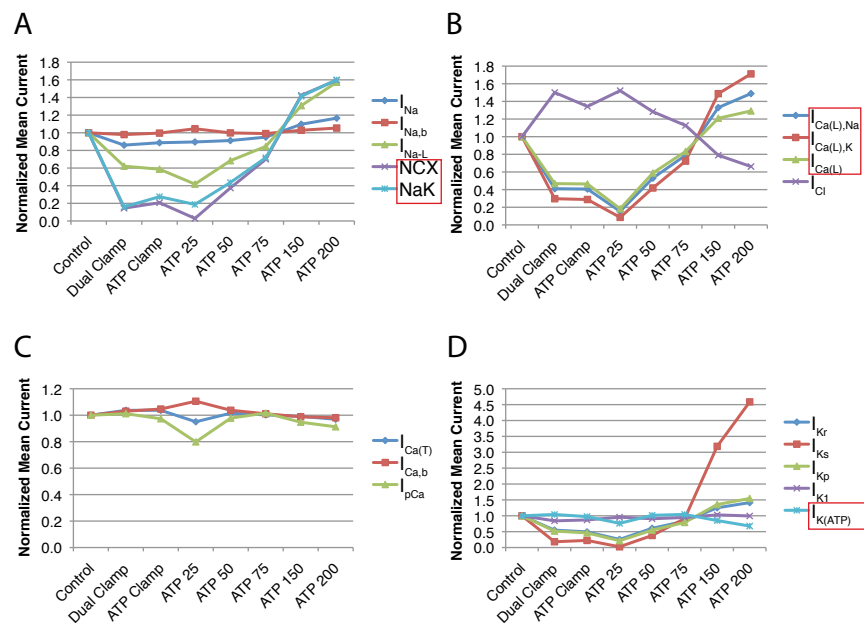

Figure S6: **Normalized mean currents throughout 10 minutes of reperfusion with variable phosphometabolite end-reperfusion target concentrations.** For each of 17 transmembrane currents, mean current in each simulation is normalized to the corresponding control. Currents that are directly modulated by pH and/or phosphometabolite concentrations are shown in red boxes.
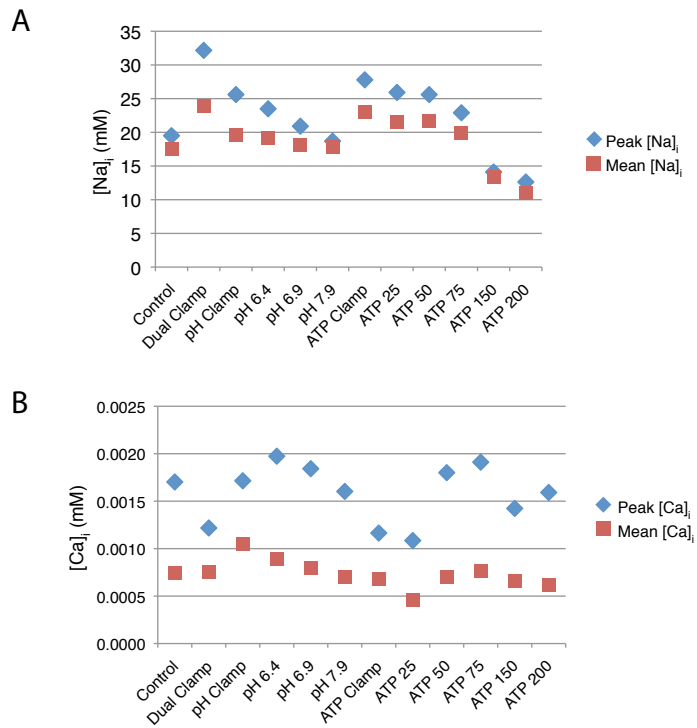

Figure S7: **Sodium and Calcium Concentrations During Simulated Reperfusion.** Peak (blue diamonds) and mean (red squares) intracellular sodium (A) and calcium (B) concentrations.
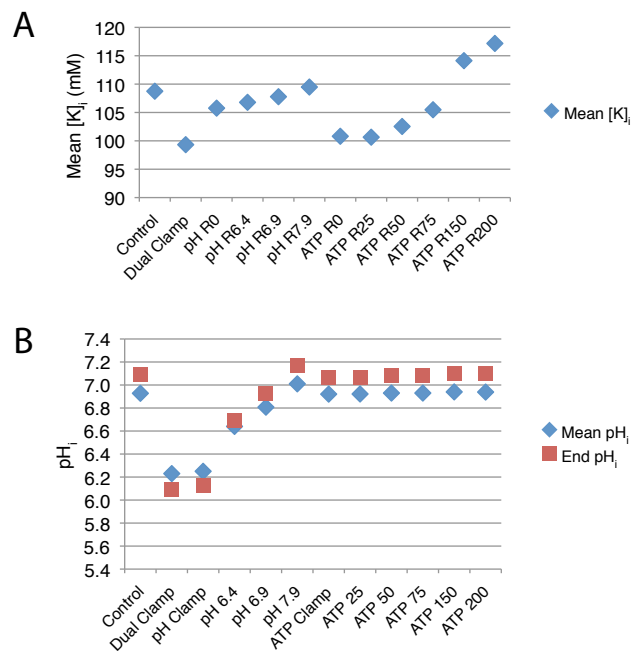

Figure S8: **Intracellular pH and Potassium Concentrations During Simulated Reperfusion.** (A) Mean intracellular potassium concentrations. (B) Mean intracellular pH (blue diamonds) and pH after 10 minutes of reperfusion (red squares).
