ARTICAL SUMMARY

Article focus

- The relationship between life event stress and chronic obstructive pulmonary disease (COPD).
- The impact of life event stress on the cognitive, mental and physical functioning of individuals with COPD.

Key messages

- Our findings showed that in individuals with COPD, life event stress unrelated to their illness experience had a worse effect in aggravating depressive symptoms and poor physical and mental functioning, more than in non-COPD individuals.

Strengths and limitations of this study

- The case definition for COPD in this study was accurately based on symptom and post-bronchial dilatation spirometric measures of chronic airflow obstruction that are diagnostic of COPD according to GOLD recommended criteria.
- The results from this general population-based study are largely free of clinical selection bias, and also controlled for important confounding by demographic and psychosocial variables in the analysis.
- Definite causal inferences cannot be made from the cross-sectional findings in this study. Further longitudinal studies are required.

Abstract

Objectives: To study the relationship between life event stress and chronic obstructive pulmonary disease (COPD) and its impact on the mental and physical functioning of individuals with COPD, which are seldom investigated.

Design: Cross-sectional study.

Participants: A population-based sample (N=497) of individuals aged 65 and above with COPD (post-bronchodilatation $FEV_1/FVC < 0.70$, N=136) and without COPD (N=277).

Outcome measures: We measured stressful life events, depressive symptoms (GDS), cognitive symptoms and function (CFQ, MMSE), and functional status (SF36-PCS and SF36-MCS) in participants with and without COPD.

Results: In two-way analysis of variance, event stress was associated with significant main effects on worse GDS ($p < 0.001$), SF36-PCS ($p = 0.008$) and SF36-MCS scores ($p < 0.001$), and with significant interaction effects in aggravating GDS score ($p < 0.001$), SF36-PCS ($p = 0.045$) and SF36-MCS ($p = 0.034$) in participants with COPD more than in non-COPD participants, controlling for potential confounders. Main effect of COPD was found for FEV_1 ($p < 0.001$) and CFQ ($p = 0.02$).

Conclusions: Life event stress was found to aggravate worse mental health and impaired functioning in individuals with COPD, much more than in those without COPD. Psychosocial stress factors should not be ignored in clinical practice when there's a relapse or flare-up of COPD symptoms.

INTRODUCTION

Chronic obstructive pulmonary disease (COPD) stands out among chronic diseases with its high and rising prevalence and mortality [1], poor quality of life, frequent hospitalization and huge societal burden of care [2]. Because patients with COPD bear a heavy burden of psychological disturbances, psychiatric morbidity, and disability in daily living activities as well, the mental health of COPD patients has received growing attention in recent years.

Psychological factors are now recognized to play important roles in the etiology of chronic illness such as type II diabetes, coronary heart disease, gastroenterological disorders and obstetric outcomes [3]. The effects of chronic stress on the hypothalamic–pituitary–adrenal (HPA) axis and neuroendocrine profiles is known to result in depression, psychological burnout or post-traumatic stress disorder (PTSD) in all ages, but in late life, as well, there is growing evidence that it may also result in cognitive disorders ranging from mild cognitive impairment (MCI) to Alzheimer's disease [4]. Studies [5-7] have reported that psychological factors, such as anxiety and depressive symptoms, are common in COPD patients and are better predictors of COPD-related quality of life than pulmonary function.

Chronic stress in COPD patients include their illness experience of various difficulties in their emotional functioning, sleep and rest, physical mobility, social interaction, activities of daily living, recreation, work and finance. An extensive literature has described the stress and anxiety provoked by breathing difficulties/dyspnea in COPD, [8, 9] including muddled thoughts, heightened emotions, extreme fear and panic and decreased physical energy.

1
2
3 The relationship between life event stress (extrinsic to illness-related experience)
4 and COPD and the impact of stress on the mental and physical health and functioning
5 of individuals with COPD has rarely been investigated [10, 11]. Life event stress relate
6 to both the occurrence of negative life events and the appraisal and perception of the
7 stressfulness of the event by the individual. Individuals with COPD may differ
8 considerably from their non-COPD counterparts with respect to their psychological
9 reaction to life situations they perceive as stressful, including the ways in which they
10 deal with the various demands posed by their respective chronic illness. Thus stress
11 cognition has a direct effect on mental health in patients with COPD [12]. Andenæs et
12 al. (2006) [13] found that there is a continual interplay between subjective appraisals of
13 stressful events and outcomes including psychological disturbances among COPD
14 patients. The limited number of studies investigating the relationship between
15 subjective stress and COPD thus warrants much further investigation [14].

33 The present study aimed to investigate the impact of life event stress on mental
34 and physical health and functioning in a population-based sample (Singapore
35 Longitudinal Aging Study) with and without COPD [15]. We hypothesized that in
36 individuals with COPD, life event stress unrelated to their illness experience had a worse
37 effect in aggravating depressive symptoms and physical and mental impairment than in
38 non-COPD individuals. This was done by investigating the main effects of life event
39 stress as well as the interaction between perceived life event stress and COPD in
40 relation to depressive symptoms and SF-36 measures of mental and physical
41 functioning.

55 **METHODS**

56 **Study Design and Participants**

1
2
3 The participants in the study were an area subsample ($n=497$) from the Singapore
4 Longitudinal Aging Study (SLAS-2), a prospective population-based cohort study of
5 aging and health of community-dwelling elderly [16]. A whole population of all older
6 adults aged 65 or older, who were residents in one district were identified from door-to-
7 door census, and invited to participate in the study. Residents who were mentally or
8 physically unable to give informed consent or participate were excluded. The response
9 rate was 78.5%. All participants signed written informed consent for the study which
10 was approved by the National University of Singapore Institutional Review Board.

21

22 COPD

23
24 We identified cases of COPD among the participants who had characteristic
25 symptoms of COPD and spirometric evidence of chronic airflow obstruction (post-
26 bronchial dilatation $FEV_1/FVC < 0.70$), in accordance with the definition recommended
27 by the Global Initiative for Chronic Obstructive Lung Disease (GOLD) [17].

31
32
33
34
35

36 Ventilatory function testing was performed using a portable, battery operated,
37 ultrasound transit-time based spirometer (Easy-One; Model 2001 Diagnostic Spirometer,
38 NDD Medical Technologies, Zurich, Switzerland). Calibration was checked daily with a 3-
39 L syringe. Forced expiratory maneuvers were performed with the respondent seated
40 with recommended guidelines and standardization of procedures: at least three
41 acceptable maneuvers, with forced vital capacity (FVC) and forced expiratory volume in
42 the first second (FEV_1) reproducible within 200 ml. Chronic airflow obstruction after
43 bronchial dilatation was defined as $FEV_1/FVC < 0.70$.

7
8

9 **Life Event Stress**

10
11 Stressful life events and self-ratings of stress were measured by an 11-item life
12 events inventory [18, 19] that excluded personal illness experiences directly related to
13 COPD. The participants were asked to indicate yes or no as to whether any of eleven life
14 events had occurred over the past year: spouse or partner die, a close friend or family
15 member die or have a serious illness (other than your spouse or partner), major
16 problems with money, a divorce or breakup, family member or close friend have a
17 divorce or breakup, major conflict with children or grandchildren, major accidents,
18 disasters, muggings, unwanted sexual experiences, robberies, or similar events, a family
19 member or close friend lose their job or retire, physically abused, verbally abused, or pet
20 die". If the participant indicated a life event(s) had occurred, he/she was asked to
21 appraise the event and indicate on a scale of 1 (did not upset me) to 3 (upset me
22 greatly) the extent it upset them. Participants who did not report the occurrence of any
23 life event or who indicated they were not affected by the event were grouped together
24 as the "no/low stress experience" group. The scale provides a life event perceived stress
25 score that ranged from 0 to 33 with a higher score indicating a participant experienced
26 a greater number of more stressful events.

47
48

49 **Depressive Symptoms**

50
51 The presence of depressive symptoms was determined by the 15-item Geriatric
52 Depression Scale (GDS-15) [20] validated for use in the local population [21]. The GDS
53 was well suited for the study because it is largely free of the measurement artefact due
54 to overlapping somatic symptoms of physical illness(es) and depression. Scores range
55
56
57
58
59
60

1
2
3 from 0 to 15, and scores of 5 or more are indicative of depression.
4
5
6

7 **Cognitive Function**

9 Cognitive function was measured using the Cognitive Failures Questionnaire (CFQ)
10 [22] and the Mini-Mental State Examination (MMSE) which are validated and widely
11 used instrument to assess global cognitive functioning [23]. The CFQ uses a 5-point
12 Likert-type scale (1 = Never, 5 = Very often) to evaluate self-reported cognitive problems
13 (e.g., "Do you need to re-read instructions several times?"). Higher CFQ scores indicate
14 more frequent cognitive problems and higher MMSE scores (0 to 30) indicate better
15 global cognitive functioning.

24

25 **Physical and Mental Functioning**

26
27 Physical and mental functional well-being was measured by the Medical Outcomes
28 Study 36-item Short Form (SF-36) [24] which has been previously validated for use in
29 Singaporeans [25]. Weighted summary measures of Physical Health Component
30 Summary (PCS) scores and Mental Health Component Summary (MCS) scores were
31 computed with higher scores indicating better physical and mental health functioning
32 and quality of life.

45 **Statistical Analysis**

46 Data analysis was performed using the software package PASW Statistics version
47 18. The relationship between life event stress and depressive symptoms, cognitive
48 function, physical and mental functioning was examined using two-way analysis of
49 variance, with statistical significance set at $p < 0.05$. The individual main effects of life
50 event stress and COPD and their interaction on depressive symptoms, cognitive function,
51 physical and mental functioning were investigated for participants with and without
52

13 14 15 16 **RESULTS**

17
18 This study consisted of 497 participants with the average age of 72.1. Among the
19 respondents, 32.9% had COPD, and 67.1% had no COPD. The proportion of respondents
20 with stressful life events in the past one year was 43.4%. The socio-demographic and
21 psychological characteristics of study participants with and without COPD are shown in
22 Table 1. No significant difference in the number of stressful life events or perceived
23 stress was observed between COPD and non-COPD participants.
24
25
26
27
28
29
30
31
32

33 Table 1 shows the scores of pulmonary and cognitive functions, depressive
34 symptoms, physical and mental functioning in participants with and without COPD. In
35 Table 2, two-way analysis of variance showed significant main effects of COPD for
36 decreased post-bronchodilator FEV₁ ($p < 0.001$) and higher CFQ scores ($p = 0.020$) after
37 adjustment of sex, age, ethnicity, smoking status, and number of chronic illness,
38 indicating impaired pulmonary and cognitive functions in participants with COPD.
39
40
41
42
43
44
45
46
47
48

49 Significant main effects of stress were found for GDS ($p < 0.001$), SF36-PCS
50 ($p = 0.008$) and SF36-MCS ($p < 0.001$) scores, and significant interactions of stress with
51 COPD were found as well for GDS ($p = 0.001$), SF36-PCS ($p = 0.045$), and SF36-MCS
52 ($p = 0.034$) scores (Table 2). The simple effects of life event stress on GDS, SF36-PCS
53 and SF36-MCS are shown for participants with and without COPD respectively (Figure 1).
54
55
56
57
58
59
60

Increasing stress score was associated with higher GDS score, lower SF12-PCS and lower SF12-MCS scores in participants with COPD, more than in those without COPD after adjusting for potential confounders, indicating the association of life event stress with worse physical and psychological health in COPD.

Table 1. Socio-demographic, pulmonary and psychological variables of study participants aged 65 or older (Singapore Longitudinal Aging Study, SLAS)

	COPD		Non-COPD	
	N	%	N	%

FEV1=Forced Expiratory Volume in the first second; CFQ=Cognitive Failure Questionnaire; MMSE=Mini-Mental State Examination; IADL=Instrumental Activities of Daily Living; GDS=the Geriatric Depression Scale; SF-36=36-Item Short-Form Healthy Survey; PCS=Physical Health Component Summary; MCS= Mental Health Component Summary.

DISCUSSION

The principal finding in this study indicated that life event stress was associated with more depressive symptoms, and worse mental and physical functioning in both COPD and non-COPD participants (main effects), but this effect was much more aggravated in COPD than in non-COPD individuals (interactive effect). To our knowledge,

1
2
3 no other studies have reported demonstrating this relationship. These results suggest
4 that individuals with COPD may be more susceptible to the adverse impact of life event
5 stress than non-COPD individuals.
6
7
8
9

10
11 Using a macro-social approach, investigators have reported an ecological study of
12 50 states in the USA showing that higher levels of stressful events was associated with
13 higher smoking prevalence as well as higher mortality from lung cancer and COPD. (11).
14 To our knowledge, this is the only circumstantial evidence suggesting an etiological link
15 between stress and the development of COPD. However, in our study, we found no
16 significant associations between life event stress and COPD in support of this link at the
17 individual level.
18
19
20
21
22
23
24
25
26
27
28

29 Among individuals with COPD in this study, it is given that the heavy burden of the
30 disease and the illness experience from difficulties in breathing and exacerbations,
31 emotional functioning, sleep and rest, physical mobility, social interaction, recreation,
32 work and finance are in themselves a principal stressor [8, 9]. This may possibly have a
33 knock-on effect on the frequency and perceived stressfulness of non-illness related
34 negative life events encountered. However, we found that COPD participants actually
35 did not report more life event occurrence or stress than non-COPD participants as a
36 result. They thus appeared to experience the same number of life events and perceived
37 them to be equally stressful as their non-COPD counterparts, but experienced
38 differentially greater psychological distress and poorer daily life functioning as a result.
39
40
41
42
43
44
45
46
47
48
49
50
51
52

53 Given the complex nature of stress and its interaction with coping ability, an
54 individual's internal psychological coping resources will determine how a negative life
55 event is perceived and appraised and impact on wellbeing [26]. Given that the
56
57
58
59
60

1
2
3 perception of stress were the same in both COPD and non-COPD individuals, differences
4
5 in psychological coping ability does not appear to explain the greater psychological
6
7 morbidity in COPD. This suggests the possibility that an underlying psychobiological
8
9 basis [26] may explain why COPD patients are more vulnerable to the adverse health
10
11 and functional impacts of stress. More studies are greatly needed given the small
12
13 number of existing studies.
14

15
16
17
18 Our secondary finding of the main effects of COPD on FEV1 was expected and thus
19
20 not surprising. However, the association of COPD with more frequent cognitive
21
22 problems was interesting, although the results for MMSE score were not significant,
23
24 possibly due to sample size limitation. These results are consistent with clinical and
25
26 population studies that indicate significant cognitive effects of COPD on deficits in
27
28 abstract reasoning, [27] complex visual motor process, [28] and verbal learning, [29]
29
30 language,[30] attention, [31] information processing speed [31-33] and verbal learning
31
32 and memory. [32, 33]
33
34
35
36

37 The present study has strengths and limitations. The case definition for COPD was
38
39 accurately based on symptom and post-bronchial dilatation spirometric measures of
40
41 chronic airflow obstruction that are diagnostic of COPD according to GOLD
42
43 recommended criteria. The measure of life event stress was modified to exclude illness-
44
45 related stress from chronic diseases in this older population. The results from this
46
47 general population-based study are largely free of clinical selection bias, and also
48
49 controlled for important confounding by demographic and psychosocial variables in the
50
51 analysis. A limitation of the study is that definite causal inferences cannot be made
52
53 from the cross-sectional findings in this study. Further longitudinal studies are required.
54
55
56
57
58
59
60

1
2
3 In conclusion, the present study found that life event stress was associated with
4 more depressive symptoms and worse mental and physical functioning in individuals
5 with COPD, much more than in those without COPD. Further studies should explore the
6 psychobiological mechanisms and the role of psychological interventions in COPD.

ARTICAL SUMMARY

Article focus

- The impact of life event stress on the mental wellbeing and quality of life of individuals with chronic obstructive pulmonary disease (COPD).

Key messages

- Our findings showed that in individuals with COPD, life event stress had a greater detrimental effect on mental health and quality of life in comparison to non-COPD individuals.

Strengths and limitations of this study

- The case definition for COPD in this study was accurately based on symptom and post-bronchial dilatation spirometric measures of chronic airflow obstruction that are diagnostic of COPD according to GOLD recommended criteria.
- The results from this general population-based study are largely free of clinical selection bias, and also controlled for important confounding by demographic and psychosocial variables in the analysis.
- Definite causal inferences cannot be made from the cross-sectional findings in this study. Further longitudinal studies are required.

Abstract

Objectives: To investigate whether life event stress was associated with greater psychological distress and poorer quality of life in older individuals with COPD, in comparison to their counterparts without COPD

Design: Cross-sectional study.

Participants: A population-based sample (N=497) of individuals aged 65 and above with COPD (post-bronchodilatation FEV₁/FVC<0.70, N=136) and without COPD (N=277).

Measurements: We measured life event stress, depressive symptoms (GDS), cognitive symptoms and function (CFQ, MMSE), and physical and mental health functional status (SF36-PCS and SF36-MCS) in participants with and without COPD.

Results: In two-way analysis of variance controlling for potential confounders, life event stress was associated with significant main effects of worse GDS ($p<0.001$), SF36-PCS ($p=0.008$) and SF36-MCS scores ($p<0.001$), and with significant interaction effects on GDS score ($p<0.001$), SF36-PCS ($p=0.045$) and SF36-MCS ($p=0.034$) in participants with COPD more than in non-COPD participants. Main effect of COPD was found for post-bronchodilator FEV₁ ($p<0.001$) and cognitive symptoms ($p=0.02$).

Conclusions: Our findings indicate that life event stress was associated with more depressive symptoms and worse quality of life in individuals with COPD, much more than in those without COPD. Further studies should explore the role of cognitive appraisal of stress, coping resources and psycho-social support in this relationship.

INTRODUCTION

Chronic obstructive pulmonary disease (COPD) stands out among chronic diseases with its high and rising prevalence and mortality [1], poor quality of life, frequent hospitalization and huge societal burden of care [2]. Because patients with COPD bear a heavy burden of psychological disturbance, psychiatric morbidity, and disability in daily living activities [3, 4], the mental health of COPD patients has received growing attention in recent years.

Life event stress is increasingly recognized to play important roles in the development and outcomes of chronic illness such as type II diabetes, coronary heart disease, gastroenterological disorders and obstetric outcomes [5]. Stress is well known to result in depression, psychological burnout, post-traumatic stress disorder (PTSD) in all ages, as well as cognitive impairment in late life [6]. Among COPD patients, an intrinsic source of stress is directly related to their illness, involving the experience of anxiety and distress provoked by breathing difficulties [7, 8], including muddled thoughts, heightened emotions, extreme fear and panic and decreased physical energy, and various difficulties in emotional functioning, sleep and rest, physical mobility, social interaction, activities of daily living, recreation, work and finance. However, the impact of life event stress in general including those extrinsic to illness-related experience on the physical and mental functioning and quality of life of individuals with COPD in comparison to non-COPD individuals has rarely been investigated [9, 10, 6]. The aim of this study was to investigate whether life event stress was associated with greater psychological distress and poorer quality of life in older individuals with COPD, in comparison to their counterparts without COPD.

The present study analyzed data collected on COPD status, life event stress, and measures of pulmonary function, cognitive function, depressive symptoms and quality of life in a population-based sample (Singapore Longitudinal Aging Study) [11] to

1
2
3 investigate the effect of life event stress on psychological functioning and quality of life.
4
5 We hypothesized that life event stress in the whole sample would be associated with
6
7 depressive symptoms and poor quality of life (main effect), but would have a stronger
8
9 association among individuals with COPD than among non-COPD individuals
10
11 (interaction), suggesting a greater detrimental effect on depressive symptoms and
12
13 quality of life. A secondary relationship analyzed in two-way analysis of variance (ANOVA)
14
15 was the main effect of COPD status (and its interaction with life event stress) on
16
17 primary outcomes of pulmonary and cognitive function, based on the known effects of
18
19 impaired pulmonary and cognitive function in COPD.
20
21
22
23

24 25 **METHODS**

26 27 **Study Design and Participants**

28
29 The participants in the study were a subsample recruited from one locality (Bukit
30
31 Merah) in the South Central region of Singapore Longitudinal Aging Study (SLAS-2), a
32
33 prospective population-based cohort study of aging and health of community-dwelling
34
35 elderly [12]. We interviewed one participant from each household who were
36
37 Singaporean citizens or permanent residents aged 65 or older who were able to give
38
39 informed consent. Those who were too frail or ill and unable to complete the interview,
40
41 for reasons such as from post-stroke aphasia, cachexia or profound dementia, were
42
43 excluded. The participants who completed interviews and provided technically
44
45 acceptable spirometric data (N=497) represented a response rate of 78.5% of the
46
47 eligible participants. All participants signed written informed consent for the study
48
49 which was approved by the National University of Singapore Institutional Review Board.
50
51

52 53 **COPD**

54
55 We identified cases of COPD among the participants who had characteristic
56
57 symptoms of COPD and spirometric evidence of chronic airflow obstruction (post-
58
59
60

1
2
3 bronchial dilatation $FEV_1/FVC < 0.70$), in accordance with the definition recommended
4
5 by the Global Initiative for Chronic Obstructive Lung Disease (GOLD) [13].
6

7 Questions from the British Medical Research Council Questionnaire on chronic
8
9 respiratory symptoms were used to elicit symptoms characteristic of COPD: chronic
10
11 cough and/or sputum lasting at least 3 months in the year and/or breathlessness on
12
13 exertion.
14

15
16 Ventilatory function testing was performed using a portable, battery operated,
17
18 ultrasound transit-time based spirometer (Easy-One; Model 2001 Diagnostic Spirometer,
19
20 NDD Medical Technologies, Zurich, Switzerland). Calibration was checked daily with a 3-
21
22 L syringe. Forced expiratory maneuvers were performed with the respondent seated
23
24 with recommended guidelines and standardization of procedures: at least three
25
26 acceptable maneuvers, with forced vital capacity (FVC) and forced expiratory volume in
27
28 the first second (FEV_1) reproducible within 200 ml. Chronic airflow obstruction as
29
30 defined as post-bronchial dilatation $FEV_1/FVC < 0.70$.
31
32

33 **Life Event Stress**

34
35 Life event stress was measured by an 11-item life events inventory [14, 15] that
36
37 excluded personal illness experiences directly related to COPD. The participants were
38
39 asked to indicate yes or no as to whether any of eleven life events had occurred over
40
41 the past year ("spouse or partner die, a close friend or family member die or have a
42
43 serious illness (other than your spouse or partner), major problems with money, a
44
45 divorce or breakup, family member or close friend have a divorce or breakup, major
46
47 conflict with children or grandchildren, major accidents, disasters, muggings, unwanted
48
49 sexual experiences, robberies, or similar events, a family member or close friend lose
50
51 their job or retire, physically abused, verbally abused, or pet die"). If the participant
52
53 indicated (a) life event(s) had occurred, he/she was asked to appraise the event and
54
55 indicate on a scale of 1 (did not upset me) to 3 (upset me greatly) the extent it upset
56
57
58
59
60

1
2
3 them. Frequency of life event stress was calculated. The scale also provides a life event
4 stress score appraised by the participant that ranged from 0 to 33 with a higher score
5 indicating a participant experienced a greater number of more stressful events.
6
7
8

9 10 **Depressive Symptoms**

11
12 The presence of depressive symptoms was determined by a depression screening
13 scale for elderly populations, the 15-item Geriatric Depression Scale (GDS-15) with
14 scores ranging from 0 to 15 [16]. The GDS was well suited for the study because it is
15 largely free of the measurement artefact due to overlapping somatic symptoms of
16 physical illness(es) and depression. In validation studies in the local older population
17 [17], translated versions of the GDS-15 have been found to be a valid and reliable
18 screening tool for depression: Cronbach's alpha of 0.80, and intraclass coefficients of
19 test-retest reliability of 0.83 and inter-rater reliability of 0.94. Using a GDS cutoff of ≥ 5 ,
20 the GDS-15 has a sensitivity of 0.97 and specificity of 0.95 (area under curve of 0.98)
21 for determining major depressive disorder according to DSM-IV criteria. Depressive
22 symptoms defined as such by $GDS \geq 5$ is clinically significant, and such cases including
23 "sub-threshold" depression, had been shown in the same population to be associated
24 with significantly poorer mental and physical health and functional status, and more
25 healthcare resource utilization compared to non-cases and were similar to or worse
26 than syndrome threshold cases of depression [18].

36
37
38
39
40
41
42
43

44 **Cognitive Function**

45
46 Cognitive function was measured using the Cognitive Failures Questionnaire (CFQ)
47 [19] and the Mini-Mental State Examination (MMSE) which were validated and widely
48 used instruments to assess global cognitive functioning [20]. The CFQ uses a 5-point
49 Likert-type scale (1 = Never, 5 = Very often) to evaluate self-reported cognitive problems
50 (e.g., "Do you need to re-read instructions several times?"). Higher CFQ scores indicate
51 more frequent cognitive problems and higher MMSE scores (0 to 30) indicate better
52
53
54
55
56
57
58
59
60

1
2
3 global cognitive functioning, and MMSE scores of 23 or less are considered to be
4
5 cognitively impaired.
6

7 **Physical and Mental Functioning**

8
9 Physical and mental functional well-being was measured by the Medical Outcomes
10 Study 36-item Short Form (SF-36) [21] which has been previously validated for use in
11 Singaporeans [22]. Weighted summary measures of Physical Health Component
12 Summary (PCS) score and Mental Health Component Summary (MCS) score were
13
14 computed with higher scores indicating better physical and mental health functioning
15
16 and quality of life.
17
18
19
20
21

22 **Statistical Analyses**

23
24 Data analysis was performed using the software package PASW Statistics version
25 18. In preliminary univariate analysis, participants with and without COPD were
26 compared with respect to differences in number of life events, and perceived stress
27 score, level of FEV1, CFQ, MMSE, GDS depression, SF-36 PCS and SF-36 MCS scores, as
28 well as potential confounding variables, sex, age, ethnicity, smoking status, number of
29 chronic diseases, using t-tests or chi-squared tests of significance. The independent
30 main effects of life event stress and COPD (independent variables) as well as the
31 interaction effects of life event stress and COPD on measures of pulmonary function,
32 depressive symptoms, cognitive function, and quality of life (dependent variables) were
33 analyzed using two-way analysis of variance (ANOVA) and general linear model which
34 adjusted for sex, age, ethnicity, smoking status, and number of chronic illness. The
35 independent variable of primary interest was life event stress, and the primary outcome
36 variables of interest were depressive symptoms and quality of life. A secondary
37 relationship analyzed in the two-way ANOVA model was the main effect of COPD status
38 (and its interaction with life event stress) on primary outcomes of pulmonary and
39 cognitive function. For the outcome variables with significant interaction of life event

1
2
3 stress and COPD, the simple effects of their relationships with life event stress score
4
5 were investigated respectively in participants with and without COPD. Statistical
6
7 significance was set at $p < 0.05$.
8
9

10 11 **RESULTS**

12
13
14 This study consisted of 497 participants with the average age of 72.1. Among the
15
16 respondents, 32.9% had COPD, and 67.1% had no COPD. The proportion of respondents
17
18 with stressful life events in the past one year was 43.4%. The socio-demographic and
19
20 psychological characteristics of study participants with and without COPD are shown in
21
22 Table 1. Participants with COPD were found to have higher mean age ($t=3.328$,
23
24 $p=0.001$), higher proportion of smokers ($\chi^2 = 20.586$, $df=3$, $p < 0.001$) and increased
25
26 number of diseases ($t=7.096$, $p < 0.001$). No significant difference in the number of life
27
28 events or perceived stress was observed between COPD and non-COPD participants
29
30 ($p > 0.05$).
31
32

33
34 Table 1 shows that compared with those without COPD, participants with COPD
35
36 had decreased post-bronchodilator FEV1 ($t=6.185$, $p < 0.001$), MMSE score ($t=3.090$,
37
38 $p=0.002$) and SF-36 PCS ($t=2.726$, $p=0.007$) score. There were no difference in CFQ
39
40 and GDS depression scores between participants with and without COPD ($p > 0.05$) in
41
42 the whole sample. Next, we evaluated the effect of life event stress on GDS, CFQ, MMSE,
43
44 SF-36 PCS and SF-36 MCS scores by subgroups of participants with COPD and without
45
46 COPD. As shown in Table 2, two-way analysis of variance in general linear model
47
48 showed significant main effects of life event stress for GDS ($F=64.500$, $df=1$, $p < 0.001$),
49
50 SF36-PCS ($F=7.054$, $df=1$, $p=0.008$) and SF36-MCS ($F=14.710$, $df=1$, $p < 0.001$) scores,
51
52 and significant interactions of life event stress with COPD were found as well for GDS
53
54 ($F=10.970$, $df=1$, $p=0.001$), SF36-PCS ($F=4.055$, $df=1$, $p=0.045$), and SF36-MCS
55
56 ($F=4.538$, $df=1$, $p=0.034$) scores. The simple effects of life event stress on GDS, SF36-
57
58
59
60

PCS and SF36-MCS are shown for participants with and without COPD respectively in Figure 1. Increasing stress score was associated with higher GDS score, lower SF12-PCS and lower SF12-MCS scores in participants with COPD, more than in those without COPD after adjusting for potential confounders, indicating the association of life event stress with worse psychological distress and poorer quality of life among individuals with COPD, in comparison to non-COPD individuals. The other significant main effect found in two-way analysis of variance was of COPD for decreased post-bronchodilator FEV₁ (F=17.458, df=1, p<0.001) and higher CFQ scores (F=5.424, df=1, p=0.020) after adjustment of sex, age, ethnicity, smoking status, and number of chronic illness, indicating impaired pulmonary and cognitive functions in participants with COPD.

Table 1. Socio-demographic, pulmonary and psychological variables of study participants aged 65 or older (Singapore Longitudinal Aging Study, SLAS)

	COPD		Non-COPD		Significant Test	p
	N	%	N	%

DISCUSSION

The principal finding in this study indicated that life event stress was associated with depressive symptoms and poor quality of life in both COPD and non-COPD participants (main effects), but showed a significantly stronger association among individuals with COPD than among non-COPD individuals (interaction), suggesting a disproportionately greater detrimental effect. To our knowledge, no other studies have reported demonstrating this relationship.

It should be noted that participants with COPD actually did not report greater frequency of occurrence or perceived stress score of non-illness related life events than non-COPD participants. Instead, individuals with COPD appeared to experience the same number of non-illness related life events and perceived them to be equally stressful as their non-COPD counterparts, yet showed disproportionately greater psychological distress and poorer quality of life. These results suggest that individuals with COPD may be more vulnerable to the adverse impact of stressful events than non-COPD individuals.

1
2
3 A greater detrimental effect of life event stress on psychological wellbeing and
4 quality of life in COPD individuals may hypothetically be explained by the possibility that
5 COPD individuals perceive and appraise stressful life events differently to individuals
6 without COPD, or that COPD individuals have poorer coping skills or fewer social and
7 economic resources, or both. We did not have measures of cognitive appraisal, coping
8 resources and social support to explore these hypotheses directly, and this is a
9 limitation of our study.
10
11
12
13
14
15
16

17
18 There are few studies that have investigated the relationship between cognitive
19 appraisal of stressful events, coping strategies and psychological distress in COPD
20 patients. A study by Andrenas and co-investigators [23] have assessed how hospitalized
21 patients with acutely exacerbated COPD appraised and coped with a recent stressful
22 event and their level of psychological distress. They reported that half of the
23 respondents tended to perceive their stressful event as representing a threat, 26% as
24 harmful, 7.6% as a loss, 4.3% as a challenge, and 11% characterized the stressful event
25 in some other ways. However, the authors found that neither types of stressful event,
26 stress intensity, primary or secondary appraisal, or number of coping strategies used
27 were significantly related to psychological distress. Only problem-solving coping
28 strategies were inversely related to psychological distress. This suggests that poor
29 coping skills may be the principal psychological problem among COPD patients that
30 contribute to their psychological distress and poor quality of life. However, further
31 studies should be conducted.

47
48

49 Our secondary finding of the main effects of COPD on FEV₁ was expected and thus
50 not surprising. However, the association of COPD with more frequent cognitive
51 problems was interesting, although the results for MMSE score were not significant
52 after adjustment in two-way ANOVA, possibly due to sample size limitation. These
53 results are consistent with clinical and population studies that indicate significant
54

9
10 The present study has strengths and limitations. The case definition for COPD is
11 accurately based on symptom and post-bronchial dilatation spirometric measures of
12 chronic airflow obstruction that are diagnostic of COPD according to GOLD
13 recommended criteria. Results from this general population-based study are largely
14 free of clinical selection bias, and also controlled for important confounding by
15 demographic and psychosocial variables in the analysis. The measure of life event
16 stress is modified to exclude illness-related stress from chronic diseases in this older
17 population. However, a limitation of the life event inventory is inter-categorical variability
18 and recall bias in the appraisal of the stressful life event [30]. In a cross-sectional study,
19 interpreting the causal relationship between stress and the health-related functional
20 outcomes can be uncertain. Further longitudinal studies are required.

31
32

33
34 Studies [31-33] have reported that mental health status, including anxiety and
35 depressive symptoms, are better predictors of COPD-related quality of life than
36 pulmonary function. The present study supports this observation and further indicates
37 that life event stress has a starkly detrimental effect on mental health and quality of life
38 in patients with COPD. While it is increasingly being recognized that the identification
39 and treatment of psychological disorders are important for improving patient centered
40 outcomes in COPD patients, there should be commensurate attention to stressful life
41 event(s) that trigger psychological disturbances and poor psycho-social functioning.
42 Psychological interventions in COPD patients that include the identification of stressful
43 life event and improving patients' coping skills may directly contribute to improving
44 psychological functioning and quality of life in COPD patients.

ARTICAL SUMMARY

Article focus

- The impact of life event stress on the mental wellbeing and quality of life of individuals with chronic obstructive pulmonary disease (COPD).

Key messages

- Our findings showed that in individuals with COPD, life event stress **had a greater detrimental effect on mental health and quality of life in comparison to non-COPD individuals.**

Strengths and limitations of this study

- The case definition for COPD in this study was accurately based on symptom and post-bronchial dilatation spirometric measures of chronic airflow obstruction that are diagnostic of COPD according to GOLD recommended criteria.
- The results from this general population-based study are largely free of clinical selection bias, and also controlled for important confounding by demographic and psychosocial variables in the analysis.
- Definite causal inferences cannot be made from the cross-sectional findings in this study. Further longitudinal studies are required.

Abstract

Objectives: To investigate whether life event stress was associated with greater psychological distress and poorer quality of life in older individuals with COPD, in comparison to their counterparts without COPD

Design: Cross-sectional study.

Participants: A population-based sample (N=497) of individuals aged 65 and above with COPD (post-bronchodilatation FEV₁/FVC<0.70, N=136) and without COPD (N=277).

Measurements: We measured life event stress, depressive symptoms (GDS), cognitive symptoms and function (CFQ, MMSE), and physical and mental health functional status (SF36-PCS and SF36-MCS) in participants with and without COPD.

Results: In two-way analysis of variance controlling for potential confounders, life event stress was associated with significant main effects of worse GDS ($p<0.001$), SF36-PCS ($p=0.008$) and SF36-MCS scores ($p<0.001$), and with significant interaction effects on GDS score ($p<0.001$), SF36-PCS ($p=0.045$) and SF36-MCS ($p=0.034$) in participants with COPD more than in non-COPD participants. Main effect of COPD was found for post-bronchodilator FEV₁ ($p<0.001$) and cognitive symptoms ($p=0.02$).

Conclusions: Our findings indicate that life event stress was associated with more depressive symptoms and worse quality of life in individuals with COPD, much more than in those without COPD. Further studies should explore the role of cognitive appraisal of stress, coping resources and psycho-social support in this relationship.

INTRODUCTION

Chronic obstructive pulmonary disease (COPD) stands out among chronic diseases with its high and rising prevalence and mortality [1], poor quality of life, frequent hospitalization and huge societal burden of care [2]. Because patients with COPD bear a heavy burden of psychological disturbance, psychiatric morbidity, and disability in daily living activities [3, 4], the mental health of COPD patients has received growing attention in recent years.

Life event stress is increasingly recognized to play important roles in the development and outcomes of chronic illness such as type II diabetes, coronary heart disease, gastroenterological disorders and obstetric outcomes [5]. Stress is well known to result in depression, psychological burnout, post-traumatic stress disorder (PTSD) in all ages, as well as cognitive impairment in late life [6]. Among COPD patients, an intrinsic source of stress is directly related to their illness, involving the experience of anxiety and distress provoked by breathing difficulties [7, 8], including muddled thoughts, heightened emotions, extreme fear and panic and decreased physical energy, and various difficulties in emotional functioning, sleep and rest, physical mobility, social interaction, activities of daily living, recreation, work and finance. However, the impact of life event stress in general including those extrinsic to illness-related experience on the physical and mental functioning and quality of life of individuals with COPD in comparison to non-COPD individuals has rarely been investigated [9, 10, 6]. The aim of this study was to investigate whether life event stress was associated with greater psychological distress and poorer quality of life in older individuals with COPD, in comparison to their counterparts without COPD.

The present study analyzed data collected on COPD status, life event stress, and measures of pulmonary function, cognitive function, depressive symptoms and quality of in a population-based sample (Singapore Longitudinal Aging Study) [11] to

1
2
3 investigate the effect of life event stress on psychological functioning and quality of life.
4
5 We hypothesized that life event stress in the whole sample would be associated with
6
7 depressive symptoms and poor quality of life (main effect), but would have a stronger
8
9 association among individuals with COPD than among non-COPD individuals
10
11 (interaction), suggesting a greater detrimental effect on depressive symptoms and
12
13 quality of life. A secondary relationship analyzed in two-way analysis of variance (ANOVA)
14
15 was the main effect of COPD status (and its interaction with life event stress) on
16
17 primary outcomes of pulmonary and cognitive function, based on the known effects of
18
19 impaired pulmonary and cognitive function in COPD.
20

25 **METHODS**

26 **Study Design and Participants**

27
28
29 The participants in the study were a subsample recruited from one locality (Bukit
30
31 Merah) in the South Central region of Singapore Longitudinal Aging Study (SLAS-2), a
32
33 prospective population-based cohort study of aging and health of community-dwelling
34
35 elderly [12]. We interviewed one participant from each household who were
36
37 Singaporean citizens or permanent residents aged 65 or older who were able to give
38
39 informed consent. Those who were too frail or ill and unable to complete the interview,
40
41 for reasons such as from post-stroke aphasia, cachexia or profound dementia, were
42
43 excluded. The participants who completed interviews and provided technically
44
45 acceptable spirometric data (N=497) represented a response rate of 78.5% of the
46
47 eligible participants. All participants signed written informed consent for the study
48
49 which was approved by the National University of Singapore Institutional Review Board.
50
51
52

53 **COPD**

54
55 We identified cases of COPD among the participants who had characteristic
56
57 symptoms of COPD and spirometric evidence of chronic airflow obstruction (post-
58
59
60

1
2
3 bronchial dilatation $FEV_1/FVC < 0.70$), in accordance with the definition recommended
4
5 by the Global Initiative for Chronic Obstructive Lung Disease (GOLD) [13].
6

7 Questions from the British Medical Research Council Questionnaire on chronic
8
9 respiratory symptoms were used to elicit symptoms characteristic of COPD: chronic
10
11 cough and/or sputum lasting at least 3 months in the year and/or breathlessness on
12
13 exertion.
14

15
16 Ventilatory function testing was performed using a portable, battery operated,
17
18 ultrasound transit-time based spirometer (Easy-One; Model 2001 Diagnostic Spirometer,
19
20 NDD Medical Technologies, Zurich, Switzerland). Calibration was checked daily with a 3-
21
22 L syringe. Forced expiratory maneuvers were performed with the respondent seated
23
24 with recommended guidelines and standardization of procedures: at least three
25
26 acceptable maneuvers, with forced vital capacity (FVC) and forced expiratory volume in
27
28 the first second (FEV_1) reproducible within 200 ml. Chronic airflow obstruction as
29
30 defined as post-bronchial dilatation $FEV_1/FVC < 0.70$.
31
32

33 **Life Event Stress**

34
35 Life event stress was measured by an 11-item life events inventory [14, 15] that
36
37 excluded personal illness experiences directly related to COPD. The participants were
38
39 asked to indicate yes or no as to whether any of eleven life events had occurred over
40
41 the past year ("spouse or partner die, a close friend or family member die or have a
42
43 serious illness (other than your spouse or partner), major problems with money, a
44
45 divorce or breakup, family member or close friend have a divorce or breakup, major
46
47 conflict with children or grandchildren, major accidents, disasters, muggings, unwanted
48
49 sexual experiences, robberies, or similar events, a family member or close friend lose
50
51 their job or retire, physically abused, verbally abused, or pet die"). If the participant
52
53 indicated (a) life event(s) had occurred, he/she was asked to appraise the event and
54
55 indicate on a scale of 1 (did not upset me) to 3 (upset me greatly) the extent it upset
56
57
58
59
60

1
2
3 them. **Frequency of life event stress was calculated.** The scale also provides a life event
4 stress score **appraised by the participant** that ranged from 0 to 33 with a higher score
5 indicating a participant experienced a greater number of more stressful events.
6
7

8 9 **Depressive Symptoms**

10
11 The presence of depressive symptoms was determined **by a depression screening**
12 **scale for elderly populations,** the 15-item Geriatric Depression Scale (GDS-15) with
13 scores ranging from 0 to 15 [16]. The GDS was well suited for the study because it is
14 largely free of the measurement artefact due to overlapping somatic symptoms of
15 physical illness(es) and depression. **In validation studies in the local older population**
16 **[17], translated versions of the GDS-15 have been found to be a valid and reliable**
17 **screening tool for depression: Cronbach's alpha of 0.80, and intraclass coefficients of**
18 **test-retest reliability of 0.83 and inter-rater reliability of 0.94. Using a GDS cutoff of >=5,**
19 **the GDS-15 has a sensitivity of 0.97 and specificity of 0.95 (area under curve of 0.98)**
20 **for determining major depressive disorder according to DSM-IV criteria. Depressive**
21 **symptoms defined as such by GDS>=5 is clinically significant, and such cases including**
22 **"sub-threshold" depression, had been shown in the same population to be associated**
23 **with significantly poorer mental and physical health and functional status, and more**
24 **healthcare resource utilization compared to non-cases and were similar to or worse**
25 **than syndrome threshold cases of depression [18].**

39
40
41
42
43

44 **Cognitive Function**

45
46 Cognitive function was measured using the Cognitive Failures Questionnaire (CFQ)
47 [19] and the Mini-Mental State Examination (MMSE) which **were** validated and widely
48 used instruments to assess global cognitive functioning [20]. The CFQ uses a 5-point
49 Likert-type scale (1 = Never, 5 = Very often) to evaluate self-reported cognitive problems
50 (e.g., "Do you need to re-read instructions several times?"). Higher CFQ scores indicate
51 more frequent cognitive problems and higher MMSE scores (0 to 30) indicate better
52
53
54
55
56
57
58
59
60

1
2
3 global cognitive functioning, and MMSE scores of 23 or less are considered to be
4
5 cognitively impaired.
6

7 **Physical and Mental Functioning**

8
9 Physical and mental functional well-being was measured by the Medical Outcomes
10 Study 36-item Short Form (SF-36) [21] which has been previously validated for use in
11 Singaporeans [22]. Weighted summary measures of Physical Health Component
12 Summary (PCS) score and Mental Health Component Summary (MCS) score were
13
14 computed with higher scores indicating better physical and mental health functioning
15
16 and quality of life.
17
18
19
20
21

22 **Statistical Analyses**

23
24 Data analysis was performed using the software package PASW Statistics version
25
26 18. In preliminary univariate analysis, participants with and without COPD were
27 compared with respect to differences in number of life events, and perceived stress
28 score, level of FEV1, CFQ, MMSE, GDS depression, SF-36 PCS and SF-36 MCS scores, as
29 well as potential confounding variables, sex, age, ethnicity, smoking status, number of
30 chronic diseases, using t-tests or chi-squared tests of significance. The independent
31 main effects of life event stress and COPD (independent variables) as well as the
32 interaction effects of life event stress and COPD on measures of pulmonary function,
33 depressive symptoms, cognitive function, and quality of life (dependent variables) were
34 analyzed using two-way analysis of variance (ANOVA) and general linear model which
35 adjusted for sex, age, ethnicity, smoking status, and number of chronic illness. The
36 independent variable of primary interest was life event stress, and the primary outcome
37 variables of interest were depressive symptoms and quality of life. A secondary
38 relationship analyzed in the two-way ANOVA model was the main effect of COPD status
39 (and its interaction with life event stress) on primary outcomes of pulmonary and
40 cognitive function. For the outcome variables with significant interaction of life event

7 significance was set at $p < 0.05$.
8
9

11 RESULTS

12
13
14 This study consisted of 497 participants with the average age of 72.1. Among the
15
16 respondents, 32.9% had COPD, and 67.1% had no COPD. The proportion of respondents
17
18 with stressful life events in the past one year was 43.4%. The socio-demographic and
19
20 psychological characteristics of study participants with and without COPD are shown in
21
22 Table 1. Participants with COPD were found to have higher mean age ($t=3.328$,
23
24 $p=0.001$), higher proportion of smokers ($\chi^2 = 20.586$, $df=3$, $p < 0.001$) and increased
25
26 number of diseases ($t=7.096$, $p < 0.001$). No significant difference in the number of life
27
28 events or perceived stress was observed between COPD and non-COPD participants
29
30 ($p > 0.05$).
31
32

33
34 Table 1 shows that compared with those without COPD, participants with COPD
35
36 had decreased post-bronchodilator FEV1 ($t=6.185$, $p < 0.001$), MMSE score ($t=3.090$,
37
38 $p=0.002$) and SF-36 PCS ($t=2.726$, $p=0.007$) score. There were no difference in CFQ
39
40 and GDS depression scores between participants with and without COPD ($p > 0.05$) in
41
42 the whole sample. Next, we evaluated the effect of life event stress on GDS, CFQ, MMSE,
43
44 SF-36 PCS and SF-36 MCS scores by subgroups of participants with COPD and without
45
46 COPD. As shown in Table 2, two-way analysis of variance in general linear model
47
48 showed significant main effects of life event stress for GDS ($F=64.500$, $df=1$, $p < 0.001$),
49
50 SF36-PCS ($F=7.054$, $df=1$, $p=0.008$) and SF36-MCS ($F=14.710$, $df=1$, $p < 0.001$) scores,
51
52 and significant interactions of life event stress with COPD were found as well for GDS
53
54 ($F=10.970$, $df=1$, $p=0.001$), SF36-PCS ($F=4.055$, $df=1$, $p=0.045$), and SF36-MCS
55
56 ($F=4.538$, $df=1$, $p=0.034$) scores. The simple effects of life event stress on GDS, SF36-
57
58
59
60

PCS and SF36-MCS are shown for participants with and without COPD respectively in Figure 1. Increasing stress score was associated with higher GDS score, lower SF12-PCS and lower SF12-MCS scores in participants with COPD, more than in those without COPD after adjusting for potential confounders, indicating the association of life event stress with worse psychological distress and poorer quality of life among individuals with COPD, in comparison to non-COPD individuals. The other significant main effect found in two-way analysis of variance was of COPD for decreased post-bronchodilator FEV₁ ($F=17.458$, $df=1$, $p<0.001$) and higher CFQ scores ($F=5.424$, $df=1$, $p=0.020$) after adjustment of sex, age, ethnicity, smoking status, and number of chronic illness, indicating impaired pulmonary and cognitive functions in participants with COPD.

Table 1. Socio-demographic, pulmonary and psychological variables of study participants aged 65 or older (Singapore Longitudinal Aging Study, SLAS)

	COPD		Non-COPD		Significant Test	p
	N	%	N	%		
Total	136	32.9	277	67.1

Table 2. Two-way ANOVA: Life event stress, COPD and mental and physical variables

	Main Effects of COPD (df=1)		Main Effects of Stress (df=1)		Interaction (df=1)	
	F	P	F	P	F	p
Post-bronchodilator FEV1	17.458	<0.001	0.323	0.570	2.057	0.152
CFQ Score	5.424	0.020	1.927	0.166	2.514	0.114
MMSE Score	1.799	0.181	1.159	0.282	0.380	0.538
GDS Depression score	2.353	0.126	64.500	<0.001	10.970	0.001
SF-36 PCS	0.432	0.512	7.054	0.008	4.055	0.045
SF-36 MCS	0.659	0.417	14.710	<0.001	4.538	0.034

Adjusted variables: sex, age, ethnicity, smoking status, and number of chronic illness. FEV1=Forced Expiratory Volume in the first second; CFQ=Cognitive Failure Questionnaire; MMSE=Mini-Mental State Examination; GDS=the Geriatric Depression Scale; SF-36=36-Item Short-Form Healthy Survey; PCS=Physical Health Component Summary; MCS= Mental Health Component Summary.

DISCUSSION

The principal finding in this study indicated that life event stress was **associated with depressive symptoms and poor quality of life** in both COPD and non-COPD participants (main effects), but showed a significantly stronger association **among individuals with COPD than among non-COPD individuals (interaction), suggesting a disproportionately greater detrimental effect**. To our knowledge, no other studies have reported demonstrating this relationship.

It should be noted that **participants with COPD** actually did not report greater **frequency of occurrence or perceived stress score of non-illness related life events** than non-COPD participants. Instead, individuals with COPD appeared to experience the same number of non-illness related life events and perceived them to be equally stressful as their non-COPD counterparts, yet showed disproportionately greater psychological distress and poorer quality of life. These results suggest that individuals with COPD may be more vulnerable to the adverse impact of stressful events than non-COPD individuals.

1
2
3 A greater detrimental effect of life event stress on psychological wellbeing and
4 quality of life in COPD individuals may hypothetically be explained by the possibility that
5 COPD individuals perceive and appraise stressful life events differently to individuals
6 without COPD, or that COPD individuals have poorer coping skills or fewer social and
7 economic resources, or both. We did not have measures of cognitive appraisal, coping
8 resources and social support to explore these hypotheses directly, and this is a
9 limitation of our study.
10
11

12
13
14
15
16
17
18 There are few studies that have investigated the relationship between cognitive
19 appraisal of stressful events, coping strategies and psychological distress in COPD
20 patients. A study by Andrenas and co-investigators [23] have assessed how hospitalized
21 patients with acutely exacerbated COPD appraised and coped with a recent stressful
22 event and their level of psychological distress. They reported that half of the
23 respondents tended to perceive their stressful event as representing a threat, 26% as
24 harmful, 7.6% as a loss, 4.3% as a challenge, and 11% characterized the stressful event
25 in some other ways. However, the authors found that neither types of stressful event,
26 stress intensity, primary or secondary appraisal, or number of coping strategies used
27 were significantly related to psychological distress. Only problem-solving coping
28 strategies were inversely related to psychological distress. This suggests that poor
29 coping skills may be the principal psychological problem among COPD patients that
30 contribute to their psychological distress and poor quality of life. However, further
31 studies should be conducted.

47
48

49 Our secondary finding of the main effects of COPD on FEV₁ was expected and thus
50 not surprising. However, the association of COPD with more frequent cognitive
51 problems was interesting, although the results for MMSE score were not significant
52 after adjustment in two-way ANOVA, possibly due to sample size limitation. These
53 results are consistent with clinical and population studies that indicate significant
54

2
3 cognitive effects of COPD on deficits in abstract reasoning [23], complex visual motor
4 process [24], and verbal learning [25], language [26], attention [27], information
5 processing speed [27-29] and verbal learning and memory [28, 29].
6
7

8
9
10 The present study has strengths and limitations. The case definition for COPD is
11 accurately based on symptom and post-bronchial dilatation spirometric measures of
12 chronic airflow obstruction that are diagnostic of COPD according to GOLD
13 recommended criteria. Results from this general population-based study are largely
14 free of clinical selection bias, and also controlled for important confounding by
15 demographic and psychosocial variables in the analysis. The measure of life event
16 stress is modified to exclude illness-related stress from chronic diseases in this older
17 population. However, a limitation of the life event inventory is inter-categorical variability
18 and recall bias in the appraisal of the stressful life event [30]. In a cross-sectional study,
19 interpreting the causal relationship between stress and the health-related functional
20 outcomes can be uncertain. Further longitudinal studies are required.

26
27
28
29
30
31
32

33
34 Studies [31-33] have reported that mental health status, including anxiety and
35 depressive symptoms, are better predictors of COPD-related quality of life than
36 pulmonary function. The present study supports this observation and further indicates
37 that life event stress has a starkly detrimental effect on mental health and quality of life
38 in patients with COPD. While it is increasingly being recognized that the identification
39 and treatment of psychological disorders are important for improving patient centered
40 outcomes in COPD patients, there should be commensurate attention to stressful life
41 event(s) that trigger psychological disturbances and poor psycho-social functioning.
42 Psychological interventions in COPD patients that include the identification of stressful
43 life event and improving patients' coping skills may directly contribute to improving
44 psychological functioning and quality of life in COPD patients.

57
58 In conclusion, the present study found that life event stress was associated with
59
60

1
2
3 more depressive symptoms and worse quality of life in individuals with COPD, much
4
5 more than in those without COPD. Further studies should explore the role of cognitive
6
7 appraisal of stress, coping resources and psycho-social support in this relationship.

ARTICAL SUMMARY

Article focus

- The impact of life event stress on the mental wellbeing and quality of life of individuals with chronic obstructive pulmonary disease (COPD).

Key messages

- Our findings showed that in individuals with COPD, life event stress had a greater detrimental effect on mental health and quality of life in comparison to non-COPD individuals.

Strengths and limitations of this study

- The case definition for COPD in this study was accurately based on symptom and post-bronchial dilatation spirometric measures of chronic airflow obstruction that are diagnostic of COPD according to GOLD recommended criteria.
- The results from this general population-based study are largely free of clinical selection bias, and also controlled for important confounding by demographic and psychosocial variables in the analysis.
- Definite causal inferences cannot be made from the cross-sectional findings in this study. Further longitudinal studies are required.

Abstract

Objectives: To investigate whether life event stress was associated with greater psychological distress and poorer quality of life in older individuals with COPD, in comparison to their counterparts without COPD

Design: Cross-sectional study.

Participants: A population-based sample (N=497) of individuals aged 65 and above with COPD (post-bronchodilatation FEV₁/FVC<0.70, N=136) and without COPD (N=277).

Measurements: We measured life event stress, depressive symptoms (GDS), cognitive symptoms and function (CFQ, MMSE), and physical and mental health functional status (SF36-PCS and SF36-MCS) in participants with and without COPD.

Results: In two-way analysis of variance controlling for potential confounders, life event stress was associated with significant main effects of worse GDS ($p<0.001$), SF36-PCS ($p=0.008$) and SF36-MCS scores ($p<0.001$), and with significant interaction effects on GDS score ($p<0.001$), SF36-PCS ($p=0.045$) and SF36-MCS ($p=0.034$) in participants with COPD more than in non-COPD participants. Main effect of COPD was found for post-bronchodilator FEV₁ ($p<0.001$) and cognitive symptoms ($p=0.02$).

Conclusions: Our findings indicate that life event stress was associated with more depressive symptoms and worse quality of life in individuals with COPD, much more than in those without COPD. Further studies should explore the role of cognitive appraisal of stress, coping resources and psycho-social support in this relationship.

INTRODUCTION

Chronic obstructive pulmonary disease (COPD) stands out among chronic diseases with its high and rising prevalence and mortality [1], poor quality of life, frequent hospitalization and huge societal burden of care [2]. Because patients with COPD bear a heavy burden of psychological disturbance, psychiatric morbidity, and disability in daily living activities [3, 4], the mental health of COPD patients has received growing attention in recent years.

Life event stress is increasingly recognized to play important roles in the development and outcomes of chronic illness such as type II diabetes, coronary heart disease, gastroenterological disorders and obstetric outcomes [5]. Stress is well known to result in depression, psychological burnout, post-traumatic stress disorder (PTSD) in all ages, as well as cognitive impairment in late life [6]. Among COPD patients, an intrinsic source of stress is directly related to their illness, involving the experience of anxiety and distress provoked by breathing difficulties [7, 8], including muddled thoughts, heightened emotions, extreme fear and panic and decreased physical energy, and various difficulties in emotional functioning, sleep and rest, physical mobility, social interaction, activities of daily living, recreation, work and finance. However, the impact of life event stress in general including those extrinsic to illness-related experience on the physical and mental functioning and quality of life of individuals with COPD in comparison to non-COPD individuals has rarely been investigated [9, 10, 6]. The aim of this study was to investigate whether life event stress was associated with greater psychological distress and poorer quality of life in older individuals with COPD, in comparison to their counterparts without COPD.

The present study analyzed data collected on COPD status, life event stress, and measures of pulmonary function, cognitive function, depressive symptoms and quality of life in a population-based sample (Singapore Longitudinal Aging Study) [11] to

1
2
3 investigate the effect of life event stress on psychological functioning and quality of life.
4
5 We hypothesized that life event stress in the whole sample would be associated with
6
7 depressive symptoms and poor quality of life (main effect), but would have a stronger
8
9 association among individuals with COPD than among non-COPD individuals
10
11 (interaction), suggesting a greater detrimental effect on depressive symptoms and
12
13 quality of life. A secondary relationship analyzed in two-way analysis of variance (ANOVA)
14
15 was the main effect of COPD status (and its interaction with life event stress) on
16
17 primary outcomes of pulmonary and cognitive function, based on the known effects of
18
19 impaired pulmonary and cognitive function in COPD.
20
21
22
23

24 25 **METHODS**

26 27 **Study Design and Participants**

28
29 The participants in the study were a subsample recruited from one locality (Bukit
30
31 Merah) in the South Central region of Singapore Longitudinal Aging Study (SLAS-2), a
32
33 prospective population-based cohort study of aging and health of community-dwelling
34
35 elderly [12]. We interviewed one participant from each household who were
36
37 Singaporean citizens or permanent residents aged 65 or older who were able to give
38
39 informed consent. Those who were too frail or ill and unable to complete the interview,
40
41 for reasons such as from post-stroke aphasia, cachexia or profound dementia, were
42
43 excluded. The participants who completed interviews and provided technically
44
45 acceptable spirometric data (N=497) represented a response rate of 78.5% of the
46
47 eligible participants. All participants signed written informed consent for the study
48
49 which was approved by the National University of Singapore Institutional Review Board.
50
51
52

53 54 **COPD**

55
56 We identified cases of COPD among the participants who had characteristic
57
58 symptoms of COPD and spirometric evidence of chronic airflow obstruction (post-
59
60

1
2
3 bronchial dilatation $FEV_1/FVC < 0.70$), in accordance with the definition recommended
4
5 by the Global Initiative for Chronic Obstructive Lung Disease (GOLD) [13].
6

7 Questions from the British Medical Research Council Questionnaire on chronic
8
9 respiratory symptoms were used to elicit symptoms characteristic of COPD: chronic
10
11 cough and/or sputum lasting at least 3 months in the year and/or breathlessness on
12
13 exertion.
14

15
16 Ventilatory function testing was performed using a portable, battery operated,
17
18 ultrasound transit-time based spirometer (Easy-One; Model 2001 Diagnostic Spirometer,
19
20 NDD Medical Technologies, Zurich, Switzerland). Calibration was checked daily with a 3-
21
22 L syringe. Forced expiratory maneuvers were performed with the respondent seated
23
24 with recommended guidelines and standardization of procedures: at least three
25
26 acceptable maneuvers, with forced vital capacity (FVC) and forced expiratory volume in
27
28 the first second (FEV_1) reproducible within 200 ml. Chronic airflow obstruction as
29
30 defined as post-bronchial dilatation $FEV_1/FVC < 0.70$.
31
32

33 **Life Event Stress**

34
35 Life event stress was measured by an 11-item life events inventory [14, 15] that
36
37 excluded personal illness experiences directly related to COPD. The participants were
38
39 asked to indicate yes or no as to whether any of eleven life events had occurred over
40
41 the past year ("spouse or partner die, a close friend or family member die or have a
42
43 serious illness (other than your spouse or partner), major problems with money, a
44
45 divorce or breakup, family member or close friend have a divorce or breakup, major
46
47 conflict with children or grandchildren, major accidents, disasters, muggings, unwanted
48
49 sexual experiences, robberies, or similar events, a family member or close friend lose
50
51 their job or retire, physically abused, verbally abused, or pet die"). If the participant
52
53 indicated (a) life event(s) had occurred, he/she was asked to appraise the event and
54
55 indicate on a scale of 1 (did not upset me) to 3 (upset me greatly) the extent it upset
56
57
58
59
60

1
2
3 them. Frequency of life event stress was calculated. The scale also provides a life event
4 stress score appraised by the participant that ranged from 0 to 33 with a higher score
5 indicating a participant experienced a greater number of more stressful events.
6
7
8

9 10 **Depressive Symptoms**

11
12 The presence of depressive symptoms was determined by a depression screening
13 scale for elderly populations, the 15-item Geriatric Depression Scale (GDS-15) with
14 scores ranging from 0 to 15 [16]. The GDS was well suited for the study because it is
15 largely free of the measurement artefact due to overlapping somatic symptoms of
16 physical illness(es) and depression. In validation studies in the local older population
17 [17], translated versions of the GDS-15 have been found to be a valid and reliable
18 screening tool for depression: Cronbach's alpha of 0.80, and intraclass coefficients of
19 test-retest reliability of 0.83 and inter-rater reliability of 0.94. Using a GDS cutoff of ≥ 5 ,
20 the GDS-15 has a sensitivity of 0.97 and specificity of 0.95 (area under curve of 0.98)
21 for determining major depressive disorder according to DSM-IV criteria. Depressive
22 symptoms defined as such by $GDS \geq 5$ is clinically significant, and such cases including
23 "sub-threshold" depression, had been shown in the same population to be associated
24 with significantly poorer mental and physical health and functional status, and more
25 healthcare resource utilization compared to non-cases and were similar to or worse
26 than syndrome threshold cases of depression [18].

40
41
42
43

44 **Cognitive Function**

45
46 Cognitive function was measured using the Cognitive Failures Questionnaire (CFQ)
47 [19] and the Mini-Mental State Examination (MMSE) which were validated and widely
48 used instruments to assess global cognitive functioning [20]. The CFQ uses a 5-point
49 Likert-type scale (1 = Never, 5 = Very often) to evaluate self-reported cognitive problems
50 (e.g., "Do you need to re-read instructions several times?"). Higher CFQ scores indicate
51 more frequent cognitive problems and higher MMSE scores (0 to 30) indicate better
52
53
54
55
56
57
58
59
60

1
2
3 global cognitive functioning, and MMSE scores of 23 or less are considered to be
4
5 cognitively impaired.
6

7 **Physical and Mental Functioning**

8
9 Physical and mental functional well-being was measured by the Medical Outcomes
10 Study 36-item Short Form (SF-36) [21] which has been previously validated for use in
11 Singaporeans [22]. Weighted summary measures of Physical Health Component
12 Summary (PCS) score and Mental Health Component Summary (MCS) score were
13
14 computed with higher scores indicating better physical and mental health functioning
15
16 and quality of life.
17
18
19
20
21

22 **Statistical Analyses**

23
24 Data analysis was performed using the software package PASW Statistics (SPSS)
25 version 18. In preliminary univariate analysis, participants with and without COPD were
26 compared with respect to differences in number of life events, and perceived stress
27 score, level of FEV1, CFQ, MMSE, GDS depression, SF-36 PCS and SF-36 MCS scores, as
28 well as potential confounding variables, sex, age, ethnicity, smoking status, number of
29 chronic diseases, using t-tests or chi-squared tests of significance. The independent
30 main effects of life event stress and COPD (independent variables) as well as the
31 interaction effects of life event stress and COPD on measures of pulmonary function,
32 depressive symptoms, cognitive function, and quality of life (dependent variables) were
33 analyzed using two-way analysis of variance (ANOVA) using generalized linear model
34 [23] which adjusted for sex, age, ethnicity, smoking status, and number of chronic
35 illness. The independent variable of primary interest was life event stress, and the
36 primary outcome variables of interest were depressive symptoms and quality of life. A
37 secondary relationship analyzed in the two-way ANOVA model was the main effect of
38 COPD status (and its interaction with life event stress) on primary outcomes of
39 pulmonary and cognitive function. For the outcome variables with significant interaction
40

58
59
60

of life event stress and COPD, the simple effects of their relationships with life event stress score were investigated respectively in participants with and without COPD. Statistical significance was set at $p < 0.05$.

RESULTS

This study consisted of 497 participants with the average age of 72.1. Among the respondents, 32.9% had COPD, and 67.1% had no COPD. The proportion of respondents with stressful life events in the past one year was 43.4%. The socio-demographic and psychological characteristics of study participants with and without COPD are shown in Table 1. Participants with COPD were found to have higher mean age ($t=3.328$, $p=0.001$), higher proportion of smokers ($\chi^2 = 20.586$, $df=3$, $p < 0.001$) and increased number of diseases ($t=7.096$, $p < 0.001$). No significant difference in the number of life events or perceived stress was observed between COPD and non-COPD participants ($p > 0.05$).

Table 1 shows that compared with those without COPD, participants with COPD had decreased post-bronchodilator FEV1 ($t=6.185$, $p < 0.001$), MMSE score ($t=3.090$, $p=0.002$) and SF-36 PCS ($t=2.726$, $p=0.007$) score. There were no difference in CFQ and GDS depression scores between participants with and without COPD ($p > 0.05$) in the whole sample. Next, we evaluated the effect of life event stress on GDS, CFQ, MMSE, SF-36 PCS and SF-36 MCS scores by subgroups of participants with COPD and without COPD. As shown in Table 2, two-way analysis of variance in general linear model showed significant main effects of life event stress for GDS ($F=64.500$, $df=1$, $p < 0.001$), SF36-PCS ($F=7.054$, $df=1$, $p=0.008$) and SF36-MCS ($F=14.710$, $df=1$, $p < 0.001$) scores, and significant interactions of life event stress with COPD were found as well for GDS ($F=10.970$, $df=1$, $p=0.001$), SF36-PCS ($F=4.055$, $df=1$, $p=0.045$), and SF36-MCS ($F=4.538$, $df=1$, $p=0.034$) scores. The simple effects of life event stress on GDS, SF36-

PCS and SF36-MCS are shown for participants with and without COPD respectively in Figure 1. Increasing stress score was associated with higher GDS score, lower SF12-PCS and lower SF12-MCS scores in participants with COPD, more than in those without COPD after adjusting for potential confounders, indicating the association of life event stress with worse psychological distress and poorer quality of life among individuals with COPD, in comparison to non-COPD individuals. The other significant main effect found in two-way analysis of variance was of COPD for decreased post-bronchodilator FEV₁ (F=17.458, df=1, p<0.001) and higher CFQ scores (F=5.424, df=1, p=0.020) after adjustment of sex, age, ethnicity, smoking status, and number of chronic illness, indicating impaired pulmonary and cognitive functions in participants with COPD.

Smoker is defined as smoking \geq 10 cigarettes daily

Table 2. Two-way ANOVA: Life event stress, COPD and mental and physical variables

	Main Effects of COPD (df=1)		Main Effects of Stress (df=1)		Interaction (df=1)	
	F	P	F	P	F	p
Post-bronchodilator FEV1	17.458	<0.001	0.323	0.570	2.057	0.152
CFQ Score	5.424	0.020	1.927	0.166	2.514	0.114
MMSE Score	1.799	0.181	1.159	0.282	0.380	0.538
GDS Depression score	2.353	0.126	64.500	<0.001	10.970	0.001
SF-36 PCS	0.432	0.512	7.054	0.008	4.055	0.045
SF-36 MCS	0.659	0.417	14.710	<0.001	4.538	0.034

Adjusted variables: sex, age, ethnicity, smoking status, and number of chronic illness.
FEV1=Forced Expiratory Volume in the first second; CFQ=Cognitive Failure Questionnaire; MMSE=Mini-Mental State Examination; GDS=the Geriatric Depression Scale; SF-36=36-Item Short-Form Healthy Survey; PCS=Physical Health Component Summary; MCS= Mental Health Component Summary.

DISCUSSION

The principal finding in this study indicated that life event stress was associated with depressive symptoms and poor quality of life in both COPD and non-COPD participants (main effects), but showed a significantly stronger association among individuals with COPD than among non-COPD individuals (interaction), suggesting a disproportionately greater detrimental effect. To our knowledge, no other studies have reported demonstrating this relationship.

It should be noted that participants with COPD actually did not report greater frequency of occurrence or perceived stress score of non-illness related life events than non-COPD participants. Instead, individuals with COPD appeared to experience the same number of non-illness related life events and perceived them to be equally stressful as their non-COPD counterparts, yet showed disproportionately greater psychological distress and poorer quality of life. These results suggest that individuals

1
2
3 with COPD may be more vulnerable to the adverse impact of stressful events than non-
4
5 COPD individuals.
6

7 A greater detrimental effect of life event stress on psychological wellbeing and
8
9 quality of life in COPD individuals may hypothetically be explained by the possibility that
10
11 COPD individuals perceive and appraise stressful life events differently to individuals
12
13 without COPD, or that COPD individuals have poorer coping skills or fewer social and
14
15 economic resources, or both. We did not have measures of cognitive appraisal, coping
16
17 resources and social support to explore these hypotheses directly, and this is a
18
19 limitation of our study.
20
21

22 There are few studies that have investigated the relationship between cognitive
23
24 appraisal of stressful events, coping strategies and psychological distress in COPD
25
26 patients. A study by Andrenas and co-investigators [24] have assessed how hospitalized
27
28 patients with acutely exacerbated COPD appraised and coped with a recent stressful
29
30 event and their level of psychological distress. They reported that half of the
31
32 respondents tended to perceive their stressful event as representing a threat, 26% as
33
34 harmful, 7.6% as a loss, 4.3% as a challenge, and 11% characterized the stressful event
35
36 in some other ways. However, the authors found that neither types of stressful event,
37
38 stress intensity, primary or secondary appraisal, or number of coping strategies used
39
40 were significantly related to psychological distress. Only problem-solving coping
41
42 strategies were inversely related to psychological distress. This suggests that poor
43
44 coping skills may be the principal psychological problem among COPD patients that
45
46 contribute to their psychological distress and poor quality of life. However, further
47
48 studies should be conducted.
49
50
51
52

53 Our secondary finding of the main effects of COPD on FEV₁ was expected and thus
54
55 not surprising. However, the association of COPD with more frequent cognitive
56
57 problems was interesting, although the results for MMSE score were not significant
58
59
60

1
2
3 after adjustment in two-way ANOVA, possibly due to sample size limitation. These
4
5 results are consistent with clinical and population studies that indicate significant
6
7 cognitive effects of COPD on deficits in abstract reasoning [25], complex visual motor
8
9 process [26], and verbal learning [27], language [28], attention [29], information
10
11 processing speed [29-31] and verbal learning and memory [30, 31].
12

13
14 The present study has strengths and limitations. The case definition for COPD is
15
16 accurately based on symptom and post-bronchial dilatation spirometric measures of
17
18 chronic airflow obstruction that are diagnostic of COPD according to GOLD
19
20 recommended criteria. Results from this general population-based study are largely
21
22 free of clinical selection bias, and also controlled for important confounding by
23
24 demographic and psychosocial variables in the analysis. The measure of life event
25
26 stress is modified to exclude illness-related stress from chronic diseases in this older
27
28 population. However, a limitation of the life event inventory is inter-categorical variability
29
30 and recall bias in the appraisal of the stressful life event [32]. In a cross-sectional study,
31
32 interpreting the causal relationship between stress and the health-related functional
33
34 outcomes can be uncertain. Further longitudinal studies are required.
35
36

37
38 Studies [33-35] have reported that mental health status, including anxiety and
39
40 depressive symptoms, are better predictors of COPD-related quality of life than
41
42 pulmonary function. The present study supports this observation and further indicates
43
44 that life event stress has a starkly detrimental effect on mental health and quality of life
45
46 in patients with COPD. More studies of the effects of stress management and coping
47
48 strategy in psychological interventions in COPD should be investigated in randomized
49
50 controlled clinical trials.
51

52
53 It is increasingly being recognized that the identification of mood and anxiety
54
55 disorders, and psychological and psychosocial interventions to improve mood and
56
57 reduce anxiety are important for improving patient centered outcomes in COPD patients.
58
59
60

1
2
3 However, in published clinical guidelines such as NICE, where the initial step care
4 management by practitioners in primary care and general hospital settings includes
5 low-intensity psychosocial interventions for patients with persistent subthreshold
6 depressive symptoms or mild to moderate depression, there appears to be little
7 attention given to identifying stressful life event(s) and supporting COPD patients
8 experiencing stressful life events to prevent the onset of mood and anxiety disorders. In
9 particular, group-based peer support, individual guided self-help based on cognitive
10 behavioural therapy (CBT) principles or computerised CBT to reduce patients'
11 vulnerability to stress may usefully include objective cognitive appraisal of stress,
12 problem-solving coping skills, and relaxation therapy to help support COPD patients
13 experiencing stressful life events.
14
15
16
17
18
19
20
21
22
23
24
25
26

27 In conclusion, the present study found that life event stress was associated with
28 more depressive symptoms and worse quality of life in individuals with COPD, much
29 more than in those without COPD. Further studies should explore the role of cognitive
30 appraisal of stress, coping resources and psycho-social support in this relationship.

STROBE 2007 (v4) Statement—Checklist of items that should be included in reports of *cross-sectional studies*

Section/Topic	Item #	Recommendation	Reported on page #
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	3
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	3
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	4
Objectives	3	State specific objectives, including any prespecified hypotheses	5
Methods			
Study design	4	Present key elements of study design early in the paper	6
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	6
Participants	6	(a) Give the eligibility criteria, and the sources and methods of selection of participants	6
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	6-8
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	6-8
Bias	9	Describe any efforts to address potential sources of bias	6-9
Study size	10	Explain how the study size was arrived at	6
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	6-9
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	8-9
		(b) Describe any methods used to examine subgroups and interactions	8-9
		(c) Explain how missing data were addressed	NA
		(d) If applicable, describe analytical methods taking account of sampling strategy	NA
		(e) Describe any sensitivity analyses	NA
Results			

Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	9
		(b) Give reasons for non-participation at each stage	6
		(c) Consider use of a flow diagram	NA
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	9
		(b) Indicate number of participants with missing data for each variable of interest	NA
Outcome data	15*	Report numbers of outcome events or summary measures	9
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	9-11
		(b) Report category boundaries when continuous variables were categorized	9-11
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	NA
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	9-11
Discussion			
Key results	18	Summarise key results with reference to study objectives	11
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	13
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	11-13
Generalisability	21	Discuss the generalisability (external validity) of the study results	11-13
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	14

*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at <http://www.plosmedicine.org/>, Annals of Internal Medicine at <http://www.annals.org/>, and Epidemiology at <http://www.epidem.com/>). ARTICAL SUMMARY

Article focus

- The impact of life event stress on the mental wellbeing and quality of life of individuals with chronic obstructive pulmonary disease (COPD).

Key messages

- Our findings showed that in individuals with COPD, life event stress had a greater detrimental effect on mental health and quality of life in comparison to non-COPD individuals.

Strengths and limitations of this study

- The case definition for COPD in this study was accurately based on symptom and post-bronchial dilatation spirometric measures of chronic airflow obstruction that are diagnostic of COPD according to GOLD recommended criteria.
- The results from this general population-based study are largely free of clinical selection bias, and also controlled for important confounding by demographic and psychosocial variables in the analysis.
- Definite causal inferences cannot be made from the cross-sectional findings in this study. Further longitudinal studies are required.

Abstract

Objectives: To investigate whether life event stress was associated with greater psychological distress and poorer quality of life in older individuals with COPD, in comparison to their counterparts without COPD

Design: Cross-sectional study.

Participants: A population-based sample (N=497) of individuals aged 65 and above with COPD (post-bronchodilatation FEV₁/FVC<0.70, N=136) and without COPD (N=277).

Measurements: We measured life event stress, depressive symptoms (GDS), cognitive symptoms and function (CFQ, MMSE), and physical and mental health functional status (SF36-PCS and SF36-MCS) in participants with and without COPD.

Results: In two-way analysis of variance controlling for potential confounders, life event stress was associated with significant main effects of worse GDS ($p<0.001$), SF36-PCS ($p=0.008$) and SF36-MCS scores ($p<0.001$), and with significant interaction effects on GDS score ($p<0.001$), SF36-PCS ($p=0.045$) and SF36-MCS ($p=0.034$) in participants with COPD more than in non-COPD participants. Main effect of COPD was found for post-bronchodilator FEV₁ ($p<0.001$) and cognitive symptoms ($p=0.02$).

Conclusions: Our findings indicate that life event stress was associated with more depressive symptoms and worse quality of life in individuals with COPD, much more than in those without COPD. Further studies should explore the role of cognitive appraisal of stress, coping resources and psycho-social support in this relationship.

INTRODUCTION

Chronic obstructive pulmonary disease (COPD) stands out among chronic diseases with its high and rising prevalence and mortality [1], poor quality of life, frequent hospitalization and huge societal burden of care [2]. Because patients with COPD bear a heavy burden of psychological disturbance, psychiatric morbidity, and disability in daily living activities [3, 4], the mental health of COPD patients has received growing attention in recent years.

Life event stress is increasingly recognized to play important roles in the development and outcomes of chronic illness such as type II diabetes, coronary heart disease, gastroenterological disorders and obstetric outcomes [5]. Stress is well known to result in depression, psychological burnout, post-traumatic stress disorder (PTSD) in all ages, as well as cognitive impairment in late life [6]. Among COPD patients, an intrinsic source of stress is directly related to their illness, involving the experience of anxiety and distress provoked by breathing difficulties [7, 8], including muddled thoughts, heightened emotions, extreme fear and panic and decreased physical energy, and various difficulties in emotional functioning, sleep and rest, physical mobility, social interaction, activities of daily living, recreation, work and finance. However, the impact of life event stress in general including those extrinsic to illness-related experience on the physical and mental functioning and quality of life of individuals with COPD in comparison to non-COPD individuals has rarely been investigated [9, 10, 6]. The aim of this study was to investigate whether life event stress was associated with greater psychological distress and poorer quality of life in older individuals with COPD, in comparison to their counterparts without COPD.

The present study analyzed data collected on COPD status, life event stress, and measures of pulmonary function, cognitive function, depressive symptoms and quality of in a population-based sample (Singapore Longitudinal Aging Study) [11] to

1
2
3 investigate the effect of life event stress on psychological functioning and quality of life.
4
5 We hypothesized that life event stress in the whole sample would be associated with
6
7 depressive symptoms and poor quality of life (main effect), but would have a stronger
8
9 association among individuals with COPD than among non-COPD individuals
10
11 (interaction), suggesting a greater detrimental effect on depressive symptoms and
12
13 quality of life. A secondary relationship analyzed in two-way analysis of variance (ANOVA)
14
15 was the main effect of COPD status (and its interaction with life event stress) on
16
17 primary outcomes of pulmonary and cognitive function, based on the known effects of
18
19 impaired pulmonary and cognitive function in COPD.
20

29 The participants in the study were a subsample recruited from one locality (Bukit
30
31 Merah) in the South Central region of Singapore Longitudinal Aging Study (SLAS-2), a
32
33 prospective population-based cohort study of aging and health of community-dwelling
34
35 elderly [12]. We interviewed one participant from each household who were
36
37 Singaporean citizens or permanent residents aged 65 or older who were able to give
38
39 informed consent. Those who were too frail or ill and unable to complete the interview,
40
41 for reasons such as from post-stroke aphasia, cachexia or profound dementia, were
42
43 excluded. The participants who completed interviews and provided technically
44
45 acceptable spirometric data (N=497) represented a response rate of 78.5% of the
46
47 eligible participants. All participants signed written informed consent for the study
48
49 which was approved by the National University of Singapore Institutional Review Board.
50
51
52

53 54 **COPD**

55
56 We identified cases of COPD among the participants who had characteristic
57
58 symptoms of COPD and spirometric evidence of chronic airflow obstruction (post-
59
60

1
2
3 bronchial dilatation $FEV_1/FVC < 0.70$), in accordance with the definition recommended
4
5 by the Global Initiative for Chronic Obstructive Lung Disease (GOLD) [13].
6

7 Questions from the British Medical Research Council Questionnaire on chronic
8
9 respiratory symptoms were used to elicit symptoms characteristic of COPD: chronic
10
11 cough and/or sputum lasting at least 3 months in the year and/or breathlessness on
12
13 exertion.
14

15
16 Ventilatory function testing was performed using a portable, battery operated,
17
18 ultrasound transit-time based spirometer (Easy-One; Model 2001 Diagnostic Spirometer,
19
20 NDD Medical Technologies, Zurich, Switzerland). Calibration was checked daily with a 3-
21
22 L syringe. Forced expiratory maneuvers were performed with the respondent seated
23
24 with recommended guidelines and standardization of procedures: at least three
25
26 acceptable maneuvers, with forced vital capacity (FVC) and forced expiratory volume in
27
28 the first second (FEV_1) reproducible within 200 ml. Chronic airflow obstruction as
29
30 defined as post-bronchial dilatation $FEV_1/FVC < 0.70$.
31
32

33 **Life Event Stress**

34
35 Life event stress was measured by an 11-item life events inventory [14, 15] that
36
37 excluded personal illness experiences directly related to COPD. The participants were
38
39 asked to indicate yes or no as to whether any of eleven life events had occurred over
40
41 the past year ("spouse or partner die, a close friend or family member die or have a
42
43 serious illness (other than your spouse or partner), major problems with money, a
44
45 divorce or breakup, family member or close friend have a divorce or breakup, major
46
47 conflict with children or grandchildren, major accidents, disasters, muggings, unwanted
48
49 sexual experiences, robberies, or similar events, a family member or close friend lose
50
51 their job or retire, physically abused, verbally abused, or pet die"). If the participant
52
53 indicated (a) life event(s) had occurred, he/she was asked to appraise the event and
54
55 indicate on a scale of 1 (did not upset me) to 3 (upset me greatly) the extent it upset
56
57
58
59
60

1
2
3 them. Frequency of life event stress was calculated. The scale also provides a life event
4 stress score appraised by the participant that ranged from 0 to 33 with a higher score
5 indicating a participant experienced a greater number of more stressful events.
6
7
8

9 10 **Depressive Symptoms**

11
12 The presence of depressive symptoms was determined by a depression screening
13 scale for elderly populations, the 15-item Geriatric Depression Scale (GDS-15) with
14 scores ranging from 0 to 15 [16]. The GDS was well suited for the study because it is
15 largely free of the measurement artefact due to overlapping somatic symptoms of
16 physical illness(es) and depression. In validation studies in the local older population
17 [17], translated versions of the GDS-15 have been found to be a valid and reliable
18 screening tool for depression: Cronbach's alpha of 0.80, and intraclass coefficients of
19 test-retest reliability of 0.83 and inter-rater reliability of 0.94. Using a GDS cutoff of ≥ 5 ,
20 the GDS-15 has a sensitivity of 0.97 and specificity of 0.95 (area under curve of 0.98)
21 for determining major depressive disorder according to DSM-IV criteria. Depressive
22 symptoms defined as such by $GDS \geq 5$ is clinically significant, and such cases including
23 "sub-threshold" depression, had been shown in the same population to be associated
24 with significantly poorer mental and physical health and functional status, and more
25 healthcare resource utilization compared to non-cases and were similar to or worse
26 than syndrome threshold cases of depression [18].

37
38
39
40
41
42
43

44 **Cognitive Function**

45
46 Cognitive function was measured using the Cognitive Failures Questionnaire (CFQ)
47 [19] and the Mini-Mental State Examination (MMSE) which were validated and widely
48 used instruments to assess global cognitive functioning [20]. The CFQ uses a 5-point
49 Likert-type scale (1 = Never, 5 = Very often) to evaluate self-reported cognitive problems
50 (e.g., "Do you need to re-read instructions several times?"). Higher CFQ scores indicate
51 more frequent cognitive problems and higher MMSE scores (0 to 30) indicate better
52
53
54
55
56
57
58
59
60

1
2
3 global cognitive functioning, and MMSE scores of 23 or less are considered to be
4
5 cognitively impaired.
6

7 **Physical and Mental Functioning**

8
9 Physical and mental functional well-being was measured by the Medical Outcomes
10 Study 36-item Short Form (SF-36) [21] which has been previously validated for use in
11 Singaporeans [22]. Weighted summary measures of Physical Health Component
12 Summary (PCS) score and Mental Health Component Summary (MCS) score were
13
14 computed with higher scores indicating better physical and mental health functioning
15
16 and quality of life.
17
18
19
20
21

22 **Statistical Analyses**

23
24 Data analysis was performed using the software package PASW Statistics (SPSS)
25 version 18. In preliminary univariate analysis, participants with and without COPD were
26 compared with respect to differences in number of life events, and perceived stress
27 score, level of FEV1, CFQ, MMSE, GDS depression, SF-36 PCS and SF-36 MCS scores, as
28 well as potential confounding variables, sex, age, ethnicity, smoking status, number of
29 chronic diseases, using t-tests or chi-squared tests of significance. The independent
30 main effects of life event stress and COPD (independent variables) as well as the
31 interaction effects of life event stress and COPD on measures of pulmonary function,
32 depressive symptoms, cognitive function, and quality of life (dependent variables) were
33 analyzed using two-way analysis of variance (ANOVA) using generalized linear model
34 [23] which adjusted for sex, age, ethnicity, smoking status, and number of chronic
35 illness. The independent variable of primary interest was life event stress, and the
36 primary outcome variables of interest were depressive symptoms and quality of life. A
37 secondary relationship analyzed in the two-way ANOVA model was the main effect of
38 COPD status (and its interaction with life event stress) on primary outcomes of
39 pulmonary and cognitive function. For the outcome variables with significant interaction

59
60

of life event stress and COPD, the simple effects of their relationships with life event stress score were investigated respectively in participants with and without COPD. Statistical significance was set at $p < 0.05$.

RESULTS

This study consisted of 497 participants with the average age of 72.1. Among the respondents, 32.9% had COPD, and 67.1% had no COPD. The proportion of respondents with stressful life events in the past one year was 43.4%. The socio-demographic and psychological characteristics of study participants with and without COPD are shown in Table 1. Participants with COPD were found to have higher mean age ($t=3.328$, $p=0.001$), higher proportion of smokers ($\chi^2 = 20.586$, $df=3$, $p < 0.001$) and increased number of diseases ($t=7.096$, $p < 0.001$). No significant difference in the number of life events or perceived stress was observed between COPD and non-COPD participants ($p > 0.05$).

Table 1 shows that compared with those without COPD, participants with COPD had decreased post-bronchodilator FEV1 ($t=6.185$, $p < 0.001$), MMSE score ($t=3.090$, $p=0.002$) and SF-36 PCS ($t=2.726$, $p=0.007$) score. There were no difference in CFQ and GDS depression scores between participants with and without COPD ($p > 0.05$) in the whole sample. Next, we evaluated the effect of life event stress on GDS, CFQ, MMSE, SF-36 PCS and SF-36 MCS scores by subgroups of participants with COPD and without COPD. As shown in Table 2, two-way analysis of variance in general linear model showed significant main effects of life event stress for GDS ($F=64.500$, $df=1$, $p < 0.001$), SF36-PCS ($F=7.054$, $df=1$, $p=0.008$) and SF36-MCS ($F=14.710$, $df=1$, $p < 0.001$) scores, and significant interactions of life event stress with COPD were found as well for GDS ($F=10.970$, $df=1$, $p=0.001$), SF36-PCS ($F=4.055$, $df=1$, $p=0.045$), and SF36-MCS ($F=4.538$, $df=1$, $p=0.034$) scores. The simple effects of life event stress on GDS, SF36-

PCS and SF36-MCS are shown for participants with and without COPD respectively in Figure 1. Increasing stress score was associated with higher GDS score, lower SF12-PCS and lower SF12-MCS scores in participants with COPD, more than in those without COPD after adjusting for potential confounders, indicating the association of life event stress with worse psychological distress and poorer quality of life among individuals with COPD, in comparison to non-COPD individuals. The other significant main effect found in two-way analysis of variance was of COPD for decreased post-bronchodilator FEV₁ (F=17.458, df=1, p<0.001) and higher CFQ scores (F=5.424, df=1, p=0.020) after adjustment of sex, age, ethnicity, smoking status, and number of chronic illness, indicating impaired pulmonary and cognitive functions in participants with COPD.

Table 1. Socio-demographic, pulmonary and psychological variables of study participants aged 65 or older (Singapore Longitudinal Aging Study, SLAS)

	COPD		Non-COPD		Significant Test	p
	N	%	N	%		
Total	136	32.9	277	67.1

GDS ≥ 5 , % (n)	5.2	(7)	2.9	(8)	$\chi^2=1.349$, df=1	0.245
SF-36 PCS	44.6	± 9.04	47.1	± 7.21	t=2.726	0.007
SF-36 MCS	54.9	± 7.83	55.1	± 6.68	t=0.353	0.724

Figures in table denote mean \pm SD or number and %.
Smoker is defined as smoking \geq 10 cigarettes daily

Table 2. Two-way ANOVA: Life event stress, COPD and mental and physical variables

	Main Effects of COPD (df=1)		Main Effects of Stress (df=1)		Interaction (df=1)	
	F	P	F	P	F	p
Post-bronchodilator FEV1	17.458	<0.001	0.323	0.570	2.057	0.152
CFQ Score	5.424	0.020	1.927	0.166	2.514	0.114
MMSE Score	1.799	0.181	1.159	0.282	0.380	0.538
GDS Depression score	2.353	0.126	64.500	<0.001	10.970	0.001
SF-36 PCS	0.432	0.512	7.054	0.008	4.055	0.045
SF-36 MCS	0.659	0.417	14.710	<0.001	4.538	0.034

Adjusted variables: sex, age, ethnicity, smoking status, and number of chronic illness.
FEV1=Forced Expiratory Volume in the first second; CFQ=Cognitive Failure Questionnaire; MMSE=Mini-Mental State Examination; GDS=the Geriatric Depression Scale; SF-36=36-Item Short-Form Healthy Survey; PCS=Physical Health Component Summary; MCS= Mental Health Component Summary.

DISCUSSION

The principal finding in this study indicated that life event stress was associated with depressive symptoms and poor quality of life in both COPD and non-COPD participants (main effects), but showed a significantly stronger association among individuals with COPD than among non-COPD individuals (interaction), suggesting a disproportionately greater detrimental effect. To our knowledge, no other studies have reported demonstrating this relationship.

It should be noted that participants with COPD actually did not report greater frequency of occurrence or perceived stress score of non-illness related life events than non-COPD participants. Instead, individuals with COPD appeared to experience the same number of non-illness related life events and perceived them to be equally stressful as their non-COPD counterparts, yet showed disproportionately greater psychological distress and poorer quality of life. These results suggest that individuals

1
2
3 with COPD may be more vulnerable to the adverse impact of stressful events than non-
4
5 COPD individuals.
6

7 A greater detrimental effect of life event stress on psychological wellbeing and
8
9 quality of life in COPD individuals may hypothetically be explained by the possibility that
10
11 COPD individuals perceive and appraise stressful life events differently to individuals
12
13 without COPD, or that COPD individuals have poorer coping skills or fewer social and
14
15 economic resources, or both. We did not have measures of cognitive appraisal, coping
16
17 resources and social support to explore these hypotheses directly, and this is a
18
19 limitation of our study.
20
21

22 There are few studies that have investigated the relationship between cognitive
23
24 appraisal of stressful events, coping strategies and psychological distress in COPD
25
26 patients. A study by Andrenas and co-investigators [24] have assessed how hospitalized
27
28 patients with acutely exacerbated COPD appraised and coped with a recent stressful
29
30 event and their level of psychological distress. They reported that half of the
31
32 respondents tended to perceive their stressful event as representing a threat, 26% as
33
34 harmful, 7.6% as a loss, 4.3% as a challenge, and 11% characterized the stressful event
35
36 in some other ways. However, the authors found that neither types of stressful event,
37
38 stress intensity, primary or secondary appraisal, or number of coping strategies used
39
40 were significantly related to psychological distress. Only problem-solving coping
41
42 strategies were inversely related to psychological distress. This suggests that poor
43
44 coping skills may be the principal psychological problem among COPD patients that
45
46 contribute to their psychological distress and poor quality of life. However, further
47
48 studies should be conducted.
49
50
51
52

53 Our secondary finding of the main effects of COPD on FEV₁ was expected and thus
54
55 not surprising. However, the association of COPD with more frequent cognitive
56
57 problems was interesting, although the results for MMSE score were not significant
58
59
60

1
2
3 after adjustment in two-way ANOVA, possibly due to sample size limitation. These
4
5 results are consistent with clinical and population studies that indicate significant
6
7 cognitive effects of COPD on deficits in abstract reasoning [25], complex visual motor
8
9 process [26], and verbal learning [27], language [28], attention [29], information
10
11 processing speed [29-31] and verbal learning and memory [30, 31].
12

13
14 The present study has strengths and limitations. The case definition for COPD is
15
16 accurately based on symptom and post-bronchial dilatation spirometric measures of
17
18 chronic airflow obstruction that are diagnostic of COPD according to GOLD
19
20 recommended criteria. Results from this general population-based study are largely
21
22 free of clinical selection bias, and also controlled for important confounding by
23
24 demographic and psychosocial variables in the analysis. The measure of life event
25
26 stress is modified to exclude illness-related stress from chronic diseases in this older
27
28 population. However, a limitation of the life event inventory is inter-categorical variability
29
30 and recall bias in the appraisal of the stressful life event [32]. In a cross-sectional study,
31
32 interpreting the causal relationship between stress and the health-related functional
33
34 outcomes can be uncertain. Further longitudinal studies are required.
35
36

37
38 Studies [33-35] have reported that mental health status, including anxiety and
39
40 depressive symptoms, are better predictors of COPD-related quality of life than
41
42 pulmonary function. The present study supports this observation and further indicates
43
44 that life event stress has a starkly detrimental effect on mental health and quality of life
45
46 in patients with COPD. **More studies of the effects of stress management and coping
47
48 strategy in psychological interventions in COPD should be investigated in randomized
49
50 controlled clinical trials.**

51
52
53 **It is increasingly being recognized that the identification of mood and anxiety
54
55 disorders, and psychological and psychosocial interventions to improve mood and
56
57 reduce anxiety are important for improving patient centered outcomes in COPD patients.**
58
59
60

1
2
3 However, in published clinical guidelines such as NICE, where the initial step care
4 management by practitioners in primary care and general hospital settings includes
5 low-intensity psychosocial interventions for patients with persistent subthreshold
6 depressive symptoms or mild to moderate depression, there appears to be little
7 attention given to identifying stressful life event(s) and supporting COPD patients
8 experiencing stressful life events to prevent the onset of mood and anxiety disorders. In
9 particular, group-based peer support, individual guided self-help based on cognitive
10 behavioural therapy (CBT) principles or computerised CBT to reduce patients'
11 vulnerability to stress may usefully include objective cognitive appraisal of stress,
12 problem-solving coping skills, and relaxation therapy to help support COPD patients
13 experiencing stressful life events.
14
15
16
17
18
19
20
21
22
23
24
25
26

27 In conclusion, the present study found that life event stress was associated with
28 more depressive symptoms and worse quality of life in individuals with COPD, much
29 more than in those without COPD. Further studies should explore the role of cognitive
30 appraisal of stress, coping resources and psycho-social support in this relationship.
