Supplementary Appendix

Statement of Author Contributions: JPP, MG, MEF, EP, AF, AM, and RLL designed the study. JPP, MG, OAW, and RLL wrote the manuscript with assistance from AM, MT, and AF. MG and ZS performed statistical analysis of the data. HF, REG, ML, HML, JMR, SL, and MST enrolled patients to the original E1900 trial, provided clinical annotation and provided assistance with analysis and interpretation of the molecular and clinical data. JR, AC, GV, RRH, RPK, and EP performed cytogenetic, flow cytometric, and molecular annotation of samples prior to DNA sequencing. JPP, PVV, ID, ST, MVDB, OA, KH, JC, AV, NDS, AH, and OAW helped to perform DNA sequencing and sequencing analysis.

Supplementary Methods

Diagnostic Samples from ECOG 1900 Clinical Trial: DNA was isolated from pretreatment bone marrow samples of 398 patients enrolled in the ECOG E1900 trial; DNA was isolated from mononuclear cells after Ficoll purification. IRB approval was obtained at Weill Cornell Medical College and Memorial Sloan Kettering Cancer Center. All genomic DNA samples were whole genome amplified using Φ 29 polymerase. Remission DNA was available from 241 patients who achieved complete remission after induction chemotherapy. Cytogenetic, fluorescent in situ hybridization, and RT-PCR for recurrent cytogenetic lesions was performed as described previously³ with central review by the ECOG Cytogenetics Committee.

Integrated Mutational Analysis: Mutational analysis of the entire coding regions of *TET2*, *ASXL1*, *DNMT3A*, *PHF6*, *WT1*, *TP53*, *EZH2*, *RUNX1*, and *PTEN* and of coding exons of *FLT3*, *HRAS*, *KRAS*, *NRAS*, *KIT*, *IDH1*, and *IDH2* with known somatic mutations was performed using PCR amplification and bidirectional Sanger sequencing as previously described.¹³ Primer sequences and PCR conditions are provided in **Table S1**. Target regions in individual patient samples were PCR amplified using standard techniques and sequenced using conventional Sanger sequencing, yielding 93.3% of all trimmed reads with an average quality score of 20 or more. All traces were reviewed manually using Mutation Surveyor (SoftGenetics, State College, PA). All variants were validated by repeat PCR amplification and Sanger resequencing of unamplified diagnostic DNA. All mutations which were not previously reported to be either somatic or germline were analyzed in matched remission DNA, when available, to determine somatic status. All patients with variants whose somatic status could not be determined were censored with regard to mutational status for the specific gene.

***NPM1*/*CEBPA* Next-Generation Sequencing Analysis:** A mononucleotide tract near the canonical frameshift mutations in *NPM1* and the high GC content of the *CEBPA* gene limited our ability to obtain sufficiently high quality Sanger sequence traces for primary mutation calling. We therefore performed pooled amplicon resequencing of *NPM1* and *CEBPA* using the SOLiD 4 system. We performed PCR amplification followed by barcoding (20 pools each with 20 samples) and SOLiD sequencing. The data was processed through the Bioscope pipeline: all variants not present in reference sequence were manually inspected and validated by repeat PCR amplification and Sanger sequencing.

Mutational Cooperativity Matrix: We adapted the Circos graphical algorithm (<http://circos.ca/>) to visualize co-occurring mutations in AML patients. The arc length corresponds to the proportion of patient with mutations in the first gene and the ribbon corresponds to the percentage of patients with a coincident mutation in the second gene. Pairwise co-occurrence of mutations is denoted only once, beginning with the first gene in the clockwise direction. Since only pairwise mutations are encoded for clarity, the arc length was adjusted to maintain the relative size of the arc and the correct proportion of patients with a single mutant allele is represented by the empty space within each mutational subset.

Statistical Analysis: Mutual exclusivity of pairs of mutations were evaluated by fourfold contingency tables and Fisher's exact test. The association between mutations and cytogenetic risk classification was tested using the chi-square test. Hierarchical clustering was performed using the Lance-Williams dissimilarity formula and complete linkage. Survival time was measured from date of randomization to date of death for those who died and date of last follow-up for those who were alive at the time of analysis. Survival probabilities were estimated using the Kaplan-Meier method and compared across mutant and wildtype patients using the log-rank test. Multivariate analyses were conducted using the Cox model.

Proportional hazards assumption was checked by testing for a non-zero slope in a regression of the scaled Schoenfeld residuals on functions of time. Many of the statistical analyses conducted in this study use Cox regression which depends critically on the assumption of proportional hazards. Supplemental Table 3 shows the results of the checks which were conducted for each mutation to determine whether the resultant survival curves (one curve for mutant and one curve for wildtype for each mutation) satisfy this assumption. A significant p-value indicates a departure from the proposal hazard assumption. Out of the 27 mutations included in this study, only a single one significantly deviated from proportional hazards (*MLL*-PTD, $p=0.04$). Considering the possible multiple testing problem, we would have expected 1-2 significances in this table by chance only hence we conclude that it is acceptable to use the Cox regression model for all mutations.

Forward model selection was employed. When necessary, such as the analyses performed in various subsets, results of the univariate analyses were used to select the variables to be included in the forward variable search. Final multivariate models informed the development of novel risk classification rules. All analyses were performed using SAS 9.2 (www.sas.com) and R 2.12 (www.r-project.org).

Supplementary Figure Legends

Figure S1. This figure shows Circos diagrams for each gene.

Figure S2. This figure shows Circos diagrams for all genes and some relevant cytogenetic abnormalities in patients within cytogenetically-defined favorable-risk (Panel A), intermediate-risk (Panel B), and unfavorable-risk (Panel C) subgroups. The percentage of patients in each cytogenetic risk category with ≥ 2 mutations is displayed in Panel D. The proportion of intermediate risk patients with 2 or more somatic mutations was significantly higher than of patients in the other 2 cytogenetic subgroups

Figure S3. This Circos diagram shows the mutual exclusivity of *IDH1*, *IDH2*, *TET2*, and *WT1*.

Figure S4. Kaplan-Meier estimates of OS according to mutational status: data are shown for OS in the entire cohort according to the mutational status of *PHF6* (Panel A) and *ASXL1* (Panel B).

Figure S5. Kaplan-Meier survival estimates are shown for *IDH2* (Panel A), *IDH2* R140 (Panel B), *IDH1* (Panel C) and the *IDH2* R172 allele (Panel D) in the entire cohort. Panel E shows both *IDH2* alleles while Panel F shows all three *IDH* alleles (p-value represents comparison of all curves). These data show that the *IDH2* R140 allele is the only *IDH* allele to have prognostic relevance in the entire cohort.

Figure S6. Kaplan-Meier estimates of OS in patients from the test cohort with core-binding factor alterations with mutations in *KIT* versus those wildtype for *KIT*. *KIT* mutations were not associated with a difference in OS when patients with any core-binding factor alteration (i.e. patients with t(8;21), inv(16), or t(16;16)) were studied (A). In contrast, *KIT* mutations were associated with a significant decrease in OS in patients bearing t(8;21) specifically (B). *KIT* mutations were not associated with adverse OS in patients with inv(16) or t(16;16) (C).

Figure S7. Kaplan-Meier survival estimates for *TET2* in cytogenetically-defined intermediate-risk patients in the cohort.

Figure S8. Kaplan-Meier survival estimates for *NPM1*-mutant patients with cytogenetically-defined intermediate-risk in the cohort. Only those with concomitant *IDH* mutations have improved survival.

Figure S9. The risk classification schema for *FLT3*-ITD wildtype (A) and mutant (B) intermediate-risk AML shown in Figure 3 is shown here for normal-karyotype patients only.

Figure S10. Mutational prognostic schema predicts outcome regardless of post-remission therapy with no transplantation (A), autologous transplantation (B), and allogeneic transplantation (C) (p-value represents comparison of all curves). Note, curves represent overall risk categories integrating cytogenetic and mutational analysis (as shown in final column in Figure 3A).

Figure S11. Kaplan-Meier estimates of OS in the entire cohort according to *DNMT3A* mutational status (Panel A and B), *MLL* translocation status (Panel C and D) or *NPM1* mutational status in patients receiving high-dose or standard-dose daunorubicin (Panels E and F). OS in patients according to treatment arm is shown in *DNMT3A* mutant (Panel A) and wild-type (Panel B) patients. Panel C shows OS in *MLL* translocated patients receiving high-dose or standard-dose daunorubicin while Panel D shows OS in non-*MLL* translocated patients depending on daunorubicin dose. OS in patients according to treatment arm is shown in *NPM1* mutant (Panel E) and wild-type (Panel F) patients as well.

Table S1. Baseline characteristics of the samples in the test, validation, and entire cohort from the ECOG E1900 trial.

Table S2. Genomic DNA primer sequences utilized for comprehensive genetic analysis. All primer sequences are displayed with M13F2/M13R2 tags.

Table S3. P-values for the test of proportional hazards for all mutations identified in the test cohort.

Table S4. Mutational frequency of genes sequenced in patients in the overall ECOG E1900 cohort and within each cytogenetic risk group.

Table S5. Co-occurrences of somatic mutations and cytogenetic abnormalities in the test cohort of 398 AML patients with *de novo* AML from the ECOG E1900 trial.

Table S6. Pairwise correlations between all genetic abnormalities.

Table S7. Frequently co-occurring genetic abnormalities.

Table S8. Mutually exclusive genetic abnormalities.

Table S9. Univariate analysis of the effects of mutations in individual genes on overall survival in the ECOG E1900 cohort.

Table S10. Univariate analysis of mutations in individual genes on intermediate-risk group in the ECOG E1900 cohort.

Table S11. Revised AML risk stratification based on integrated genetic analysis with frequency and number of patients in each genetic risk category displayed.

Table S12. Genetic prognostic schema is independent of treatment-related mortality and chemotherapy resistance in the test cohort and the entire cohort of the analyzed ECOG E1900 patients.

Table S13. Differential response to high-dose versus standard-dose daunorubicin induction chemotherapy based on genotype of AML patients.

PTEN	2	1	2	1
TP53	2	0	1	6
HRAS	0	0	0	0
EZH2	0	0	0	0

1) ITD – internal tandem duplication; TKD – tyrosine kinase domain mutation.

2) PTD – partial tandem duplication.

* denotes mutations which were significantly enriched in a specific cytogenetic risk group compared to the entire cohort (p<0.01 for all).

Table S5: Co-occurrences of somatic mutations and cytogenetic abnormalities in the test cohort of 398 AML patients with *de novo* AML from the ECOG E1900 trial.

Table S11: Revised AML Risk Stratification Based on Integrated Mutational Analysis (frequency of patients per cytogenetic/mutational risk category in the Test cohort is shown).

Cytogenetic Classification	Mutations		Test cohort (% (N))	Validation cohort (% (N))	Overall Risk
Inversion (16), t(8;21)	Any		19.7% (71)	15.5% (13)	Favorable
Normal Karyotype or Intermediate Risk Cytogenetic Lesions	<i>FLT3</i> -ITD negative	<i>NPM1</i> and <i>IDH1/2</i> mutant	5.8% (21)	7.1% (6)	Intermediate
	<i>FLT3</i> -ITD negative	<i>ASXL1</i> , <i>MLL</i> -PTD, <i>PHF6</i> and <i>TET2</i> -wildtype	35.5% (129)	27.4% (23)	
	<i>FLT3</i> -ITD negative or positive	<i>CEBPA</i> mutant			
	<i>FLT3</i> -ITD positive	<i>MLL</i> -PTD, <i>TET2</i> , and <i>DNMT3A</i> wildtype, and trisomy 8 negative	20.9% (76)	21.4% (18)	Unfavorable
	<i>FLT3</i> -ITD negative	<i>TET2</i> , <i>MLL</i> -PTD, <i>ASXL1</i> , or <i>PHF6</i> mutant			
	<i>FLT3</i> -ITD positive	<i>TET2</i> , <i>MLL</i> -PTD, <i>DNMT3A</i> mutant or trisomy 8			
Unfavorable	Any		18.2% (66)	28.6% (24)	

Table S12. Genetic prognostic schema is independent of treatment-related mortality¹ and chemotherapy resistance² in the test cohort and the entire cohort of the analyzed ECOG E1900 patients.

Test cohort (n=398)			
	Hazard Ratio	Confidence Interval	p-value
Favorable	Reference		<0.001
Intermediate	1.88	1.15 – 3.05	
Unfavorable	6.16	3.83 – 9.88	
Entire cohort (n=502)			
	Hazard Ratio	Confidence Interval	p-value
Favorable	Reference		<0.001
Intermediate	1.83	1.18 – 2.85	
Unfavorable	5.76	3.76 – 8.82	

¹Treatment-related mortality defined as death within 30 days after beginning induction chemotherapy.

²Chemotherapy resistance defined as failure to enter complete remission despite not incurring treatment-related mortality, or relapse.

Table S13. Differential response to high-dose versus standard-dose daunorubicin induction chemotherapy based on genotype of AML patients.

- 1) P-value calculated by Log-rank test.
- 2) P-value adjusted for multiple testing by a step-down Holm procedure (see Supplementary Methods). “-“ indicates adjusted p-value not performed.
