

Microarray analysis in liver following burn and CLP

Supplementary materials

Quantitative real-time PCR

qPCR gene expression studies were performed for genes of interest (GOI) as validation of the microarray results. The RNA samples were amplified with Nugen WT Pico Kit (Part# 3300-A01) (NuGEN Technologies Inc, San Carlos, CA, USA). RNA was reversed transcribed into DNA. Then cDNA samples were diluted by 100 times. All the samples were tested in triplicates. qPCR was performed using the ABI 7900 HT Sequence Sequence Detection System (TaqMan; Applied Biosystems, Foster City, CA, USA) using standard fluorescent chemistries and thermal cycling conditions. Primer and probe sequences were designed for each experimental gene's mRNA sequence using Primer Express software (Applied Biosystems) as shown in **Table 3**. For the gene of interest, 6-10 ng of cDNA was mixed with 20 μ M FWR/Rvse and 10 μ M (UPL) Probe (UPL). The reference gene GAPDH was added into Rodent GAPDH control kit ABI (Part No.4308313) (TaqMan; Applied Biosystems, Foster City, CA, USA) with 10 μ M FWR/Rvse and 20 μ M Probe. Thermal cycling conditions were as specified by the manufacturer: 50°C for 2 min, 95°C for 10 min, and 40 cycles as follows: 95°C for 15 s, ramp to 60°C for 1 min.

Analysis of qPCR data

For the analysis of the qPCR results, averaged normalized data for each experimental gene was compared between B_CLP groups and SB_CLP groups using the $2^{-\Delta\Delta C_t}$ method.

Microarray analysis in liver following burn and CLP
