Supplementary Methods and Results

Supplementary Methods

Pathogenicity of the swine- and human-origin H1N1/2009 viruses

5-week-old female specific pathogen free (SPF) BALB/c mice were infected with 50 μ L of Jia6/10 and LN/09 viruses with the titer of 10³TCID₅₀ and monitored daily for the signs of disease and mortality till to the 14th day. Body weights were measured daily and the mice lost more than 20% of body weight were euthanized. Six mice in each group were euthanized respectively on day 3 day 5 to collect lung tissues for subsequent virus titer determination, pathological analysis and quantification of cellular factors. The lung tissues were homogenated and the supernatants were collected for detection of the production of cytokines IL-1 β , IL-6 and TNF α by enzyme-linked immunosorbent assay (ELISA) according to the manufacturer's protocol (Dakewe, Shenzhen, China). Each test had three replicates. The viral titer detection and histopathological analysis of the mouse lung tissues were proceed as previously described¹. Appropriate lung tissues infected by Jia6/10 and LN/09 as well as another H5N1 influenza virus (A/duck/Hubei/hangmei01/2006 [HM/06]) were fixed in 10% neutral buffered formalin and routinely processed into paraffin. Sections of 4-mm thickness were cut for hematoxylin and eosin staining for histopathologic evaluation as previously described¹.

Animal experiments and lung tissues collection

Stock viruses were prepared by propagating the A/Liaoning/1/2009 (H1N1) (LN/09) (GenBank accession numbers: JX403975-82) and A/swine/Nanchang/F9/2010 (H1N1) (Jia6/10) (GenBank accession numbers: JF275925-32) influenza viruses for one passage in MDCK cells for 40 to 48 h at 37 °C in a 5% CO₂ incubator. The infectious viral titers were determined using the Reed

and Muench method² and expressed as log10 of the 50% tissue culture infective dose per 1.0 mL of fluid (TCID₅₀/mL). Six-week-old female BALB/c mice were divided into 3 groups with 6 mice each group. One group of mice was infected with LN/09; the second group was infected with Jia6/10, and the final group was incubated with an equivalent PBS buffer. Each mouse was infected intranasally with 50 µL of a cellular virus stock fluid diluted in PBS to 10³ TCID₅₀. On day 3 and day 5 post-infection, three mice were euthanized and their lung tissues were harvested immediately after slaughter, cut into pieces, frozen and stored in liquid nitrogen. The animal studies were approved by Experimental Animal Center, Institute of Medicine, Hubei Province, China (No. 00018734).

RNA preparation and high-throughput sequencing

The stored lung tissue was placed separately in liquid nitrogen, ground thoroughly to a fine powder and then lysed with TRIzol reagent (Invitrogen, USA). Total RNA was extracted using the RNeasy Mini Kit (QIAGEN, Germany) according to the manufacturer's protocol. The quality and concentration of the RNA were determined by an Agilent 2100 Bioanalyzer (260 nm/280 nm). The cDNA libraries were generated using the Illumina mRNASEQ kit and then clonally amplified on a cluster generation station using Illumina version 4 cluster generation reagents. The resulting libraries were then sequenced on a Genome Analyzer IIx using Illumina version 4.0 sequencing reagents, which generated single reads of 76 nucleotides. Image analysis, base calling and error estimation were performed using Illumina Analysis Pipeline software (version 2.6).

Bioinformatics analysis

To systematically characterize the transcriptome of virus-infected tissue, we employed various publicly available tools for the mapping, assembly, and

quantification of transcripts, and we integrated these tools with additional informatics filtering steps to enrich the results for the most robust transcriptome construction. The details of the bioinformatics analysis are provided below.

Read alignment and assembly

Due to the BALB/c mice genome sequence and related annotation are lacking at the moment. So we mapped the RNA-seq reads to the C57BL/6 (mm9) reference genome with a relatively relax criteria for read mapping which allowed maximum two mismatch. We retained transcripts corresponding to mRNAs, pseudogenes or long non-coding RNAs from the Ensembl (release 63, 2011-04-20), the RefSeq (release 37, 2011-03-04), the UCSC (2011-03-02) and the Vega (release 44, 2011-08-11) as the reference annotation information. And the RNA-seq reads from each sample were aligned to the mouse reference genome using TopHat software (version 1.3.2; allowing maximum two mismatches) as previously described³. Then, the aligned reads from TopHat mapping were subjected to the Cufflinks program (version 1.1.0; with default parameters) for ab initio transcript assembly⁴.

Discovery of splice junctions, NTRs and alternative spliced exons

We prepared two databases of possible splice junctions in this study. The first database was based on the merged annotated transcripts and the second database was derived by identifying new junctions using TopHat based on RNA-seq data without relying on the genome annotations. And the identification of the splice junctions, the NTRs and the AS events had been performed as previous studies^{5,6}.

Quantification of gene expression levels

The gene expression levels were computed according to previous study and presented as RPKM value⁷. For hierarchical clustering analysis, the clustering software Cluster 3.0⁸ was used to perform the complete linkage hierarchical

clustering on both the genes and the samples, using uncentered Pearson's correlation as the distance measure. The clustering results were visualized using the Java Treeview program⁹.

Statistical analysis

All of the statistical analyses were performed using the R language (<http://www.r-project.org/>). For the gene set analysis based on the GO term enrichment methods, GO::TermFinder¹⁰ was used to detect the significantly enriched GO terms for the interested gene sets, which were compared to the genome-wide background with an adjusted P value (FDR) cutoff of 0.05.

Supplementary Results

Identification and description of the NTRs

The RNA-seq has the greatest potential thus far to discover and annotate novel transcripts¹¹. In the present study, 355 NTRs containing 622 multi-exon transcripts were identified based on the transcriptome data (Supplemental Table S1).

At first glance, the overall expression pattern of the NTRs demonstrated diversity across the Jia6/10- and LN/09-infected groups (Supplementary Fig. S2A). Notably, many of these regions were regulated by virus infection. As shown in an example in Supplementary Fig. S2B, a novel transcript significantly increased in the virus-infected samples. The NTRs might closely relate to the virus infection and play a role in the interaction between the virus and the mouse lungs. Meanwhile, some NTRs also appeared in the non-influenza virus-infected mouse lungs, indicating that these NTRs might be associated with the normal biological development of mouse. Furthermore, we found that 77.6% of the NTRs only had two exons, and the NTRs had fewer exons per transcript (approximately 2.3) than the average protein-coding genes (approximately 7.7) (Supplementary Fig. S2C). We also observed that the novel

transcripts were (on average) approximately one-third the length of the protein-coding transcripts (median size of 453 bp for the NTRs versus 1,331 bp for the protein-coding transcripts) (Supplementary Fig. S2D). The structure and expression level features of the NTRs examined here were consistent with previous observation that NTRs had shorter exons and tissue-specific expression than the annotated protein-coding genes⁶.

Analysis of splice variants

Alternative splicing (AS), through which a single gene could produce multiple mRNA and protein isoforms, is an important mechanism for the biodiversity of transcriptome and proteome¹². It has been postulated as a principal contributor of the evolution of the phenotypic complexity in mammals⁵. To systematically investigate the splicing dynamics between the normal and the virus-infected tissues, a computational analysis was performed to categorize all of the splicing models into eight common types of AS events: 1) intron retention (IR), 2) cassette exons (CE), 3) mutually exclusive exons (MEE), 4) coordinate cassette exons (CCE), 5) alternative 5' splice sites (A5SS), 6) alternative 3' splice sites (A3SS), 7) alternative first exons (AFE) and 8) alternative last exons (ALE)¹³ (Supplementary Fig. S3A). A total of 39,736 splicing events comprised of these eight AS events were identified with 11,250 multi-exonic genes containing at least one AS event. The predominated AS events observed in the annotated transcriptome were AFE (27.9%), followed by CE (17.7%), A3'SS (17.0%) and ALE (12.2%). Reads supporting both alternative isoforms were observed for 57.3% of these events (Supplementary Fig. S3A).

To assess the extent of the splicing changes upon influenza virus infection, a total of 337 splicing events from 261 genes that changed significantly in the virus-infected groups (false discovery rate (FDR) < 0.05; Supplementary Table S2)

were identified. Notably, although several events were constitutively identified in both the Jia6/10- and LN/09-infected mouse lungs, a higher frequency of virus-specific events was observed in the Jia6/10-infected tissue than in the LN/09-infected tissue and/or in the day 5 groups compared to the day 3 groups (Supplementary Fig. S3A), which suggested that Jia6/10 exerted a greater influence on the transcriptome or proteome complexity than the LN/09 virus, and the complexity was increasing along the process of virus infection.

As the two examples showed here, the splicing events involved the *Tnfrsf19* and the *Gbp5* genes were significantly activated by the virus infection. The *Tnfrsf19* gene splicing event involved an AFE model (Supplementary Fig. S3B), where the exon was preferentially included in the virus-infected cells. While, after the virus infection, an exon of the *Gbp5* gene was activated and the gene displayed a CE model for the second isoform (Supplementary Fig. S3C).

Collectively, most of the NTRs and AS events were regulated by virus infection and displayed distinct changing models and/or magnitude between Jia6/10 and LN/09 infected mouse lung tissues. The identified NTRs and AS events were important contributor to the transcriptome complexity and might closely relate to the pathogenicity of the viruses.

note:blue color represents downregulated genes;

red color represents upregulated genes;

blank color represents different changing trend in Jia6/10 and LN/10 infection group on day 3 and day5.

Table S4. Gene ontology (GO) analysis of differentially expressed genes after virus infection

GO ID	GO Term	Up-regulated genes				Down-regulated genes			
		Corrected p-value	No. of genes	Gene list		Corrected p-value	No. of genes	Gene list

Note: a: nucleotide of the virus gene before | after the infection by Jia6/10 and LN/09 viruses;

b: read number of the nucleotide supported by the transcriptome data;

c: three different nucleotides (A, C, G) mutation appeared after Jia6/10 and LN/09 infection.

Table S6. Expression level of the genes associated with chemokines and pro- and anti-oxidation stimulation (compared the expression level of the chemokines and pro-and anti-oxidation genes between Jia6/10 and Hm/06)
