ARTICLE SUMMARY

1) Article Focus

- This paper compares consumers' self-reported confidence in health care in the United Kingdom and the United States, using 2010 survey responses gathered by the Commonwealth Fund.
- We sought to determine whether self-reported confidence in healthcare differed between the United Kingdom and the United States, as well as by rurality or urbanicity.

2) Key Messages

- We believe that while much current political and academic discourse surrounding healthcare is focused on systems, providers, and policy, patient experience and perception may also be key to understanding and responding to healthcare issues.
- Suburban residents in the US expressed higher confidence in both receiving effective treatment and affording care than their rural and urban counterparts; however, overall confidence in the US was significantly lower than in the UK, where residence type did not have an effect.
- These findings warrant examination of the causes for relative confidence levels in both regions, as well as among residence types within the US. Suburban healthcare in the US should be further examined to identify why it is associated with higher patient confidence levels.

3) Strengths and Limitations

Strengths:

- Confidence can serve as a useful proxy for understanding patient attitudes and behaviors and has implications distinct from other more commonly discussed notions such as satisfaction or trust, in that confidence implies components of self-efficacy.
- This analysis contributes to an ongoing discourse about healthcare systems by calling attention to the role of patient perspectives in this conversation. Such data provide a potential gauge of public response to policies affecting healthcare.

Limitations:

- Confidence is a subjective concept, and interpretations of the concept of confidence in one group may not be generalizable to another for semantic, cultural, and situational reasons.
- Similarly, the definition of "rurality" is not fixed, especially when comparing rural areas across different countries.

ABSTRACT:

Objective: Confidence in healthcare may influence patients' utilization of healthcare resources and perceptions of healthcare quality. We sought to determine whether self-reported confidence in healthcare differed between the United Kingdom and the United States, as well as by rurality or urbanicity.

Design: A secondary analysis of a subset of survey questions regarding self-reported confidence in healthcare from the 2010 Commonwealth Fund International Health Policy Survey.

Setting: Telephone survey in the United Kingdom and the United States.

Participants: Our final analysis included 1,511 UK residents (688 rural, 446 suburban, 372 urban) and 2,501 US residents (536 rural, 1,294 suburban, 671 urban).

Outcome measures: Questions assessed respondents' confidence in the effectiveness and affordability of treatment. We compared survey outcomes from these questions between, and within, the two regions and among, and within, residence types (rural, suburban, and urban).

Results: Significant differences were found in self-reported confidence in healthcare between the UK and US, among residence types, and between the two regions within residence types. Reported levels were higher in the UK. Within regions, significant differences by residence type were found for the US but not the UK. Within the US, suburban respondents had the highest self-reported confidence in healthcare.

Conclusions: Significant differences exist between the UK and US in confidence in healthcare. In the US but not in the UK, self-reported confidence is related to residence type. Within countries, significant differences by residence type were found for the US but not the UK. Our findings warrant examination of causes for relative confidence levels between regions and among US residence types.

INTRODUCTION:

A focus on patient-centered care has emerged in recent years in discussions of health care delivery, systems of care, and direct care settings.[1] Patient-centered care is typically defined as care that is responsive to individual patient needs and which facilitates shared decision making among patients, family members, and providers.[2] The patient experience is highly subjective and hinges on emotional, circumstantial, and interpretive factors that are difficult to quantify and compare across groups. While patient satisfaction has been discussed at some length, another subjective measure, the concept of patient confidence, is one that has been understudied thus far.[3] For the purposes this paper, we define confidence in healthcare as a person's reliance on and trust in themselves and in their health system in yielding favorable health outcomes.

Discussions about healthcare dominate the current political and popular discourse. While the focus often centers around fiscal, cultural, and ethical concerns,[4, 5] the tendency to criticize or praise a healthcare system may also be linked to biases, generalizations, and narratives based on personal experiences and beliefs. Confidence in a health system could play a key role in shaping patients' utilization, assessments, and stated desires regarding their health. Nationalized healthcare in the United Kingdom is often held up as a counterpoint to the multi-payer system in the United States;[6] thus a comparison of patient confidence in these two regions could be helpful in better assessing the role of confidence in discussions and decisions pertaining to healthcare.

The UK has been found to have one of the highest levels of patient satisfaction among European countries,[7] and comparisons of health outcomes in the UK and US have explored physical and mental domains of health-related quality of life in the two regions.[6] US-based confidence surveys have explored perceptions and comprehension of health reform[8] and consumer confidence within the US.[9] Building on this research and on public interest in co-examining the UK and US systems, we see value in comparing the two regions on the subjective measure of confidence.

Confidence levels from a patient's perspective may influence both positive and negative health outcomes. Some factors related to confidence include patient satisfaction, medical skepticism, trust in government, health literacy, and management and organization of the healthcare system.[10-13] The efficiency and effectiveness of a healthcare system from a patient's perspective might affect a patient's adherence to medical therapies, self-efficacy, and determination to improve personal health.[14] In the case of medical skepticism, mistrust in the healthcare system could result in a patient's complete denial of any sort of service, believing that she or he is capable of taking care of their own health with no assistance.[10] Personal characteristics that have been found to influence health confidence are health/disease status, age, insurance coverage/ability to pay, the present health service infrastructure, language/cultural barriers, ethnicity, sex/gender, employment status, and socioeconomic position.[15] All of these factors may affect a health system's delivery of programs and services if the community they work with does not feel confident in the system's ability to address issues specific to their community. Nonetheless, confidence and its effects on health continue to be understudied.

We sought to determine whether self-reported confidence in healthcare differed between the United Kingdom and the United States, as well as by rurality or urbanicity.

METHODS:

Between March and June of 2010, the Commonwealth Fund's International Health Policy Survey was conducted via telephone surveys in 11 countries and from which we used data from the United Kingdom and the United States.[16] The survey contained questions about health and health care experiences, perceptions, coverage, and costs. Households in both the UK and the US were selected using random digit dialing, and both samples were drawn to be representative of the geographic population distribution in each country or region.[16] Alaska and Hawaii were excluded from the US survey. Collection methods are further described elsewhere.[16]

For this analysis, residence categorization data from the UK was recoded from four categories into three categories for side-by-side comparison with the US. American respondents were categorized as living in either a rural, suburban, or urban area. UK respondents were originally categorized as living in a village/rural area, a small town, a large town or suburb of a city, or an urban area. Village/rural area and small town were combined into one "rural" group.

Three questions in the survey sought to assess participants' confidence levels. These questions were: 1. "How confident are you that if you become seriously ill, you will receive the most effective treatment, including drugs and diagnostic tests?" 2. "How confident are you that if you become seriously ill, you will be able to afford the care you need?" and 3. How confident are you that you can control and manage your health problems?" Responses to all three questions were measured on a six-item Likert scale with the items "very confident," "confident," "not very confident," "not at all confident," "unsure," and "decline to answer."

Pearson's chi-square tests were used to compare relative frequencies between and within regions and between and within residence types. To compare data ordinally, rank sum tests were also conducted. Mann-Whitney U tests measured differences between the UK and US overall, as well as between the UK and US within each residence type. Kruskal-Wallis tests were used for rank-sum comparisons between residence types overall and between residence types within each region or country. Significance was set at $p \leq 0.05$. All statistical analyses were conducted using Stata, Version 12 (StataCorp. 2011. Stata Statistical Software: Release 12. College Station, TX: StataCorp LP).

RESULTS:

Participants:

One thousand, five hundred and eleven (1,511) UK residents and 2,501 US residents responded to the survey. The UK response rate was 24%, and the US response rate was 26%.[16] Eighty-seven percent (86.8%) of UK and 77.0% of US respondents identified as white. Women made up 48.4% of the UK sample and 61.7% of the US respondents. Forty-six percent (45.5%) of UK respondents lived in rural areas or small towns. Only 21.4% of US respondents identified their residence as rural, while over half (51.7%) lived in suburban areas. Demographics are described further in Table 1. Data was missing for five UK respondents on residence type, so these five participants were excluded from the data analysis.

Table 1. Demographic Characteristics, by Region/Country of Residence and Residence Type

[a]Missing data from 5 UK respondents on Residence Type

[b]Missing data from 141 UK and 232 US respondents on Income Level

Outcomes:

A limited sample of respondents from each country (n=471 UK and 1,486 US) answered the question "How confident are you that you can control and manage your health problems?" Over 90% of this limited pool of respondents in both regions answered "very confident" or "confident," so a statistical comparison was not meaningful, and that question was removed from the final analysis. Results of the other two confidence questions, "How confident are you that if you become seriously ill, you will receive the most effective treatment, including drugs and

diagnostic tests?" and "How confident are you that if you become seriously ill, you will be able to afford the care you need?" are described as follows.

Confidence in receiving effective treatment:
Overall, the differences between the UK and the US for responses on confidence in receiving effective treatment were significant for both chi-square and Mann-Whitney U tests (Table 2).

Table 2. Survey responses to the question:
How confident are you that if you become seriously ill, you will receive the most effective treatment, including drugs and diagnostic tests?

	Confidence Level (%)								
	Very confident	Confident	Not very confident	Not at all confident	Not sure	Decline to answer	χ^2	Mann-Whitney U	Kruskal-Wallis
Comparison between Region/Country[a]							p<0.001*	p<0.001*	
United Kingdom	32.0%	61.3%	5.6%	0.7%	0.4%	0.0%

[a,c]Chi-square and Mann-Whitney U tests

[b,d]Chi-square and Kruskal-Wallis tests

Ninety-three percent (93.3%) of UK residents were confident or very confident in receiving effective treatment, compared with 73.3% of US residents. Within residence types, Mann-Whitney and chi-square tests revealed statistically significant differences between countries (all p<0.01). Among residence types overall, differences were also significant based on both chi-square and Kruskal-Wallis tests. Within each country, there were only statistically significant differences by residence type in the US (χ 2 p=0.003, Kruskal-Wallis p=0.001) and not in the UK (χ 2 p=0.817, Kruskal-Wallis p=0.781).

Confidence in affording care:
Statistically significant differences were found between the UK and US via chi-square and Mann-Whitney tests (Table 3).

Table 3. Survey responses to the question:
How confident are you that if you become seriously ill, you will be able to afford the care you need?

	Confidence Level (%)

	Very confident	Confident	Not very confident	Not at all confident	Not sure	Decline to answer	χ^2	Mann-Whitney U	Kruskal-Wallis

[a,c]Chi-square and Mann-Whitney U tests

[b,d]Chi-square and Kruskal-Wallis tests

In the UK, 91% of respondents were confident or very confident in their ability to afford healthcare, versus 61.6% in the US. Within residence types there were also statistically significant differences. Among residence types overall, there were only statistically significant differences based the chi-square test, not on the Kruskal-Wallis. Within the UK and US, as for the effective treatment question, differences in confidence based on residence type were only statistically significant for US respondents (US: $\chi 2$ p=0.001, Kruskal-Wallis p=0.001; UK $\chi 2$ p=0.339, Kruskal-Wallis p=0.084).

A descriptive analysis of responses by residence type in the US revealed that suburban respondents had the highest percentage (76.3%) of confident or very confident ratings in effectiveness of treatment, versus 69.4% in rural areas and 70.4% in urban areas. Regarding ability to afford treatment in the US, 65.4% of suburban residents were confident or very confident, compared with 56.8% in rural areas and 58.2% in urban areas.

DISCUSSION:

Significant differences were found between the UK and the US in health confidence. Suburban residents in the US expressed higher confidence in both receiving effective treatment and affording care than their rural and urban counterparts; however, overall confidence in the US was significantly lower than in the UK, where residence type did not have an effect. The effect of the overall difference between residence types may be moderated by the lack of difference in the UK. Our findings are supported by a previous study which found that in the UK the public is happier than in the US (and other countries surveyed) regarding their healthcare system and are least likely to be worried about future health care needs.[17]

These findings warrant examination of the causes for relative confidence levels in both regions,

as well as among residence types within the US. Specifically, the larger percentage of suburban Americans who rated their confidence as high implies that factors in the suburban environment may contribute to a sense of control or reliability. While disparities in access, safety, and quality of care between rural and urban areas are well-documented,[18, 19] our findings suggest that exploring the suburban healthcare environment could provide insight into US healthcare attitudes, especially given that 50% of Americans live in suburban areas.[20]

This analysis contributes to an ongoing discourse about healthcare systems by calling attention to the role of patient perspectives in this conversation. How end users perceive their system to be serving them or accessible to them is an important factor in assessing, maintaining, and revising healthcare legislation, pricing, standards of care, and communication frameworks. Data on confidence, particularly in patient assessments of future or hypothetical health circumstances, provide insight into how patients might make decisions in planning and paying for health care. Such data also provide a potential gauge of public response to policies affecting healthcare. Our findings that UK residents have greater self-reported confidence in healthcare might suggest higher levels of trust and perceived system stability as well as a perspective of confidence as a social norm. The outcomes determined here may be viewed not only as markers of patients' personal experiences with health care, but also as indicators of the sociocultural context in which each healthcare system functions.

We acknowledge the inability to assess wholly the concept of confidence. Confidence in one group may not be generalizable to another for semantic, cultural, and situational reasons. However, confidence can serve as a useful proxy for understanding patient attitudes and behaviors and has implications distinct from other more commonly discussed notions such as satisfaction or trust, in that confidence implies components of self-efficacy. For both populations sampled in this study, data was gathered from English-speaking respondents who answered survey questions about confidence written in English, and both groups received the questions worded identically, providing some consistency in how confidence might be interpreted here across groups.

There remain a number of constraints and limitations on our data and subsequent conclusions which must be taken into consideration. The issue of confidence itself is somewhat troublesome given its inherently subjective nature and the myriad factors that can contribute to individual confidence. Age, gender, ethnicity, education, socioeconomic status, health status, and health literacy are just a few of the many factors that can potentially contribute to confidence in healthcare, and each might also serve as a potential confounder. Notably, two of the three Commonwealth Fund questions involve notions of personal forecasting ("if I become seriously ill, then..."), which may be more subject to biases than questions about conditions that are already present.

Furthermore, the definition of "rurality" can be problematic, especially given the disparate categories for the UK and US. Although the recoding of these categories to combine "village/ rural area" and "small town' in the UK was rather simple, definitions of what constitutes rural, suburban, and other descriptors varies culturally and contextually. It is also notable that four healthcare systems are actually included in the Commonwealth Fund's category for the UK. Scotland, Wales, Northern Ireland, and England each maintain unique healthcare systems, and

despite their similarities, this must be noted when assigning value to UK health system efficacy in comparison to the US.

CONCLUSION:
Our analyses revealed significant differences between the UK and the US in self-reported confidence levels, suggesting a disparity between these regions and their systems in the provision of equitable healthcare to all residents. Suburban healthcare in the US should be further examined to identify why it is associated with higher patient confidence levels. The findings of this study build on existing literature and may provide insight for policy developers and health practitioners working with rural, suburban, and urban communities. Patient confidence would be an interesting and culturally relevant measure for future survey projects to explore in more detail.

ACKNOWLEDGEMENTS:
The authors wish to thank Cathy Schoen, Michelle Doty, Robin Osborn, David Squires, and Kristof Stremikis from the Commonwealth Fund for providing the data set and input on the final draft of this manuscript.

ARTICLE SUMMARY

1) Article Focus

- This paper compares consumers' self-reported confidence in health care in the United Kingdom and the United States, using 2010 survey responses gathered by the Commonwealth Fund.
- We sought to determine whether self-reported confidence in healthcare differed between the United Kingdom and the United States, as well as by rurality or urbanicity.

2) Key Messages

- We believe that while much current political and academic discourse surrounding healthcare is focused on systems, providers, and policy, patient experience and perception may also be key to understanding and responding to healthcare issues.
- Suburban residents in the US expressed higher confidence in both receiving effective treatment and affording care than their rural and urban counterparts; however, overall confidence in the US was significantly lower than in the UK, where residence type did not have an effect.
- These findings warrant examination of the causes for relative confidence levels in both regions, as well as among residence types within the US. Suburban healthcare in the US should be further examined to identify why it is associated with higher patient confidence levels.

3) Strengths and Limitations

Strengths:

- Confidence can serve as a useful proxy for understanding patient attitudes and behaviors and has implications distinct from other more commonly discussed notions such as satisfaction or trust, in that confidence implies components of self-efficacy.
- This analysis contributes to an ongoing discourse about healthcare systems by calling attention to the role of patient perspectives in this conversation. Such data provide a potential gauge of public response to policies affecting healthcare.

Limitations:

- Confidence is a subjective concept, and interpretations of the concept of confidence in one group may not be generalizable to another for semantic, cultural, and situational reasons.
- Similarly, the definition of "rurality" is not fixed, especially when comparing rural areas across different countries.

ABSTRACT:

Objective: Confidence in healthcare may influence patients' utilization of healthcare resources and perceptions of healthcare quality. We sought to determine whether self-reported confidence in healthcare differed between the United Kingdom and the United States, as well as by rurality or urbanicity.

Design: A secondary analysis of a subset of survey questions regarding self-reported confidence in healthcare from the 2010 Commonwealth Fund International Health Policy Survey.

Setting: Telephone survey of participants from the United Kingdom and the United States.

Participants: Our final analysis included 1,511 UK residents (688 rural, 446 suburban, 372 urban) and 2,501 US residents (536 rural, 1,294 suburban, 671 urban).

Outcome measures: Questions assessed respondents' confidence in the effectiveness and affordability of treatment. We compared survey outcomes from these questions between, and within, the two regions and among, and within, residence types (rural, suburban, and urban).

Results: Significant differences were found in self-reported confidence in healthcare between the UK and US, among residence types, and between the two regions within residence types. Reported levels were higher in the UK. Within regions, significant differences by residence type were found for the US but not the UK. Within the US, suburban respondents had the highest self-reported confidence in healthcare.

Conclusions: Significant differences exist between the UK and US in confidence in healthcare. In the US but not in the UK, self-reported confidence is related to residence type. Within countries, significant differences by residence type were found for the US but not the UK. Our findings warrant examination of causes for relative confidence levels between regions and among US residence types.

INTRODUCTION:

A focus on patient-centered care has emerged in recent years in discussions of health care delivery, systems of care, and direct care settings.[1, 2] Patient-centred care is typically defined as care that is responsive to individual patient needs and which facilitates shared decision making among patients, family members, and providers.[3] The patient experience is highly subjective and hinges on emotional, circumstantial, and interpretive factors that are difficult to quantify and compare across groups.

While patient satisfaction has been discussed at some length [4, 5], another subjective measure, the concept of patient confidence in health care, is one that has been understudied thus far. The question of provider confidence in patients' abilities to care for themselves has been studied, but this research did not look into patients' own confidence regarding their health and health care.[6] A survey conducted in the United States (US) explored the public's confidence in affording and accessing care.[7] Another US survey measured respondents' confidence in their ability to overcome disease without medical assistance.[8]

Related issues like patient satisfaction and self-efficacy have been explored in depth,[4, 5, 9, 10] but these notions are distinct from confidence. Confidence is defined as assurance or reliance on oneself, on other people or on things, or in circumstances.[11] Self-efficacy is related to personal sense of capacity/capability,[12] while satisfaction is a response or impression following an experience.[13] Consumer confidence in health care has been surveyed,[14] but this is a facet of confidence focused more narrowly on consumer spending. For the purposes of this paper, we draw on the dictionary definition[11] and previous health confidence survey questions[7] to define confidence in healthcare as a person's reliance on and trust in themselves and in their health system in yielding favorable health outcomes.

With the passage and implementation of the Patient Protection and Affordable Care Act in the US, discussions about healthcare have dominated recent political and popular discourse.[15, 16] While the focus often centers around fiscal, cultural, and ethical concerns, the tendency to criticize or praise a healthcare system may also be linked to biases, generalizations, and narratives based on personal experiences and beliefs.[17, 18] Confidence in one's individual health care and in the health system may play a key role in shaping patients' utilization, assessments, and stated desires regarding their health. Single-payer, publicly administered healthcare in the United Kingdom (UK) is often held up as a counterpoint to the more fragmented multi-payer, fee-for-service system in the US;[19, 20, 21] thus a comparison of patient confidence in these two regions could be helpful in better assessing the role of confidence in discussions and decisions pertaining to healthcare.

The UK has been found to have one of the highest levels of patient satisfaction among European countries,[22] and comparisons of health outcomes in the UK and US have explored physical and mental domains of health-related quality of life in the two regions.[23] US-based confidence surveys have explored perceptions and comprehension of health reform[7] and consumer confidence within the US.[14] Building on this research and on public interest in co-examining the UK and US systems, we see value in comparing the two regions on the subjective measure of confidence.

Some factors related to confidence in healthcare include patient satisfaction, medical skepticism, trust in government, health literacy, and management and organization of the healthcare system.[23-26] The efficiency and effectiveness of a healthcare system from a patient's perspective might affect patient adherence to medical therapies, self-efficacy, and determination to improve personal health.[27] In the case of medical skepticism, mistrust in the healthcare system could result in a patient's complete denial of any sort of service, believing that she or he is capable of taking care of their own health with no assistance.[23] Personal characteristics that have been found to influence confidence in personal health management are disease status, age, insurance coverage/ability to pay, the present health service infrastructure, language and cultural barriers, ethnicity, sex/gender, employment status, and socioeconomic position.[8] These factors may affect a health system's delivery of programs and services if community members do not feel confident in the system's ability to address issues specific to their community. Rural, lower resource communities with poorer system performance have been associated with low patient satisfaction,[28] and a Canadian study found that place of residence contributed to patient satisfaction.[29] Factors such as perceived or actual facility or system performance and residence type may influence patient confidence in healthcare.

We sought to determine whether self-reported confidence in healthcare differed between the United Kingdom and the United States, as well as by rurality or urbanicity.

METHODS:

Between March and June of 2010, the Commonwealth Fund's International Health Policy Survey was conducted via telephone surveys in 11 countries and from which we used data from the United Kingdom and the United States.[30] The survey contained questions about health and health care experiences, perceptions, coverage, and costs. Households in both the UK and the US were selected using random digit dialing, and both samples were drawn to be representative of the geographic population distribution in each country or region.[30] Alaska and Hawaii were excluded from the US survey. Collection methods are further described elsewhere.[30]

For this analysis, residence categorization data from the UK was recoded from four categories into three categories for side-by-side comparison with the US. American respondents were categorized as living in either a rural, suburban, or urban area. UK respondents were originally categorized as living in a village/rural area, a small town, a large town or suburb of a city, or an urban area. Village/rural area and small town were combined into one "rural" group.

Three questions in the survey sought to assess participants' confidence levels. These questions were: 1. "How confident are you that if you become seriously ill, you will receive the most effective treatment, including drugs and diagnostic tests?" 2. "How confident are you that if you become seriously ill, you will be able to afford the care you need?" and 3. How confident are you that you can control and manage your health problems?" Responses to all three questions were measured on a six-item Likert scale with the items "very confident," "confident," "not very confident," "not at all confident," "unsure," and "decline to answer."

Pearson's chi-square tests were used to compare relative frequencies between and within regions and between and within residence types. To compare data ordinally, rank sum tests were also conducted. Mann-Whitney U tests measured differences between the UK and US overall, as well as between the UK and US within each residence type. Kruskal-Wallis tests were used for rank-

sum comparisons between residence types overall and between residence types within each region or country. Significance was set at $p \leq 0.05$. All statistical analyses were conducted using Stata, Version 12 (StataCorp. 2011. Stata Statistical Software: Release 12. College Station, TX: StataCorp LP).

RESULTS:

Participants:

One thousand, five hundred and eleven (1,511) UK residents and 2,501 US residents responded to the survey. The UK response rate was 24%, and the US response rate was 26%.[16] Eighty-seven percent (86.8%) of UK and 77.0% of US respondents identified as white. Women made up 48.4% of the UK sample and 61.7% of the US respondents. Forty-six percent (45.5%) of UK respondents lived in rural areas or small towns. Only 21.4% of US respondents identified their residence as rural, while over half (51.7%) lived in suburban areas. Demographics are described further in Table 1. Data was missing for five UK respondents on residence type, so these five participants were excluded from the data analysis.

Table 1. Demographic Characteristics, by Region/Country of Residence and Residence Type

[a]Missing data from 5 UK respondents on Residence Type

[b]Missing data from 141 UK and 232 US respondents on Income Level

Outcomes:

A limited sample of respondents from each country (n=471 UK and 1,486 US) answered the question "How confident are you that you can control and manage your health problems?" Over 90% of this limited pool of respondents in both regions answered "very confident" or "confident," so a statistical comparison was not meaningful, and that question was removed from the final analysis. Results of the other two confidence questions, "How confident are you that if you become seriously ill, you will receive the most effective treatment, including drugs and diagnostic tests?" and "How confident are you that if you become seriously ill, you will be able to afford the care you need?" are described as follows.

Confidence in receiving effective treatment:

Overall, the differences between the UK and the US for responses on confidence in receiving effective treatment were significant for both chi-square and Mann-Whitney U tests (Table 2).

Table 2. Survey responses to the question:

How confident are you that if you become seriously ill, you will receive the most effective treatment, including drugs and diagnostic tests?

	Confidence Level (%)								
	Very confident	Confident	Not very confident	Not at all confident	Not sure	Decline to answer	χ^2	Mann-Whitney U	Kruskal-Wallis
Comparison between Region/Country[a]							p<0.001*	p<0.001*	
United Kingdom	32.0%	61.3%	5.6%	0.7%	0.4%	0.0%			
United States	34.6%	38.7%	16.0%	9.1%	1.3%	0.3%			
Comparison between Residence Types[b]							p=0.004*		p=0.004*
Rural	32.0%	51.2%	10.2%	5.2%	1.2%	0.1%			
Suburban	35.9%	44.9%	12.4%	5.6%	1.0%	0.2%

United States	p=0.003*	p=0.001*

[a,c]Chi-square and Mann-Whitney U tests

[b,d]Chi-square and Kruskal-Wallis tests

Ninety-three percent (93.3%) of UK residents were confident or very confident in receiving effective treatment, compared with 73.3% of US residents. Within residence types, Mann-Whitney and chi-square tests revealed statistically significant differences between countries (all p<0.01). Among residence types overall, differences were also significant based on both chi-square and Kruskal-Wallis tests. Within each country, there were only statistically significant differences by residence type in the US (χ 2 p=0.003, Kruskal-Wallis p=0.001) and not in the UK (χ 2 p=0.817, Kruskal-Wallis p=0.781).

Confidence in affording care:
Statistically significant differences were found between the UK and US via chi-square and Mann-Whitney tests (Table 3).

Table 3. Survey responses to the question:
How confident are you that if you become seriously ill, you will be able to afford the care you need?

	Confidence Level (%)								
	Very confident	Confident	Not very confident	Not at all confident	Not sure	Decline to answer	χ^2	Mann-Whitney U	Kruskal-Wallis

United States							p=0.001*		p=0.001*

[a,c]Chi-square and Mann-Whitney U tests

[b,d]Chi-square and Kruskal-Wallis tests

In the UK, 91% of respondents were confident or very confident in their ability to afford healthcare, versus 61.6% in the US. Within residence types there were also statistically significant differences. Among residence types overall, there were only statistically significant differences based the chi-square test, not on the Kruskal-Wallis. Within the UK and US, as for the effective treatment question, differences in confidence based on residence type were only

statistically significant for US respondents (US: $\chi 2$ p=0.001, Kruskal-Wallis p=0.001; UK $\chi 2$ p=0.339, Kruskal-Wallis p=0.084).

A descriptive analysis of responses by residence type in the US revealed that suburban respondents had the highest percentage (76.3%) of confident or very confident ratings in effectiveness of treatment, versus 69.4% in rural areas and 70.4% in urban areas. Regarding ability to afford treatment in the US, 65.4% of suburban residents were confident or very confident, compared with 56.8% in rural areas and 58.2% in urban areas.

DISCUSSION:

Significant differences were found between the UK and the US in health confidence. Suburban residents in the US expressed higher confidence in both receiving effective treatment and affording care than their rural and urban counterparts; however, overall confidence in the US was significantly lower than in the UK, where residence type did not have an effect. The effect of the overall difference between residence types may be moderated by the lack of difference in the UK. Our findings are supported by a previous study which found that in the UK the public is happier than in the US (and other countries surveyed) regarding their healthcare system and are least likely to be worried about future health care needs.[31] Higher confidence in healthcare in the UK than in the US may be related to differences between healthcare systems, to cultural and political differences, or to differing social norms that may influence interpretations in answering questions about confidence. Examining causes for higher or lower respondent confidence could illuminate future directions for health system decision makers in both regions.

In addition to exploring the causes for relative confidence levels in regions, these findings also warrant closer examination of the different confidence levels among residence types within the US. Lower confidence in the rural US may not be simply attributable to health insurance coverage, as rural US coverage is highly variable.[32] Other factors such as income, race/ethnicity, age, and socio-cultural factors may combine to influence rural confidence.[32] The larger percentage of suburban Americans who rated their confidence as high implies that factors in the suburban environment may contribute to a sense of control or reliability. While disparities in access, safety, and quality of care between rural and urban areas are well-documented,[33, 34] our findings suggest that exploring the suburban healthcare environment could provide insight into US healthcare attitudes, especially given that 50% of Americans live in suburban areas.[35] Studies have explored rural, suburban, and urban localities as factors in health information management,[36] minority access to care,[37] and telemedicine satisfaction[38] with varying results for each measure. More targeted research on place of residence in health care confidence and quality may be advisable.

This analysis contributes to an ongoing discourse about the advantages and disadvantages of UK and US healthcare systems by calling attention to the role of patient perspectives in this conversation. How end users perceive their system to be serving them or accessible to them is an important factor in assessing, maintaining, and revising healthcare legislation, pricing, standards of care, and communication frameworks. Data on confidence, particularly in patient assessments of future or hypothetical health circumstances, provide insight into how patients might make decisions in planning and paying for health care. Such data also provide a potential gauge of public response to policies affecting healthcare. Our findings that UK residents have greater self-

reported confidence in healthcare might suggest higher levels of perceived reliability and system stability in their single-payer system as well as a perspective of confidence as a social norm. The outcomes determined here may be viewed not only as markers of patients' personal experiences with health care, but also as indicators of the sociocultural context in which each healthcare system functions. Comparing responses to confidence questions with responses about insurance status, accessibility of care, and personal factors such as income and age could be an area for follow up research that could clarify the extent to which expressions of confidence might be associated with system features versus other factors.

We acknowledge the inability to assess wholly the concept of confidence. Confidence in one group may not be generalizable to another for semantic, cultural, and situational reasons. However, confidence can serve as a useful proxy for understanding patient attitudes and behaviors and has implications distinct from other more commonly discussed notions such as satisfaction or trust, in that confidence implies components of self-efficacy. For both populations sampled in this study, data was gathered from English-speaking respondents who answered survey questions about confidence written in English, and both groups received the questions worded identically, providing some consistency in how confidence might be interpreted here across groups.

There remain a number of constraints and limitations on our data and subsequent conclusions which must be taken into consideration. The issue of confidence itself is somewhat troublesome given its inherently subjective nature and the myriad factors that can contribute to individual confidence. Age, gender, ethnicity, education, socioeconomic status, health status, and health literacy are just a few of the many factors that can potentially contribute to confidence in healthcare, and each might also serve as a potential confounder. Notably, two of the three Commonwealth Fund questions involve notions of personal forecasting ("if I become seriously ill, then..."), which may be more subject to biases than questions about conditions that are already present.

The definition of "rurality" can be problematic, especially given the disparate categories for the UK and US. Although the recoding of these categories to combine "village/ rural area" and "small town' in the UK was rather simple, definitions of what constitutes rural, suburban, and other descriptors varies culturally and contextually. It is also notable that four healthcare systems are included in the Commonwealth Fund's category for the UK. Scotland, Wales, Northern Ireland, and England each maintain unique healthcare systems, and despite their similarities, distinctions should be acknowledged when assigning value to UK health system effectiveness and quality in comparison with the US. For example, while universal registration for primary care is consistent across the four countries' health systems, there are key differences in prescription charges from country to country and in how each country is implementing recent reforms.[39] In addition to considering these distinct countries in future comparisons, other health care systems such as Canada's, which combines public funding with private sector delivery[40], could provide a useful point of comparison for future analyses of confidence in health care.

CONCLUSION:

Our analyses revealed significant differences between the UK and the US in self-reported

confidence levels, suggesting a disparity between these regions and their systems in the provision of equitable healthcare to all residents. Suburban healthcare in the US should be further examined to identify why it is associated with higher patient confidence levels. The findings of this study build on existing literature and may provide insight for policy developers and health practitioners working with rural, suburban, and urban communities. Patient confidence would be an interesting and culturally relevant measure for future survey projects to explore in more detail.

ACKNOWLEDGEMENTS:
The authors wish to thank Cathy Schoen, Michelle Doty, Robin Osborn, David Squires, and Kristof Stremikis from the Commonwealth Fund for providing the data set and input on the final draft of this manuscript.

ARTICLE SUMMARY

1) Article Focus

- This paper compares consumers' self-reported confidence in health care in the United Kingdom and the United States, using 2010 survey responses gathered by the Commonwealth Fund.
- We sought to determine whether self-reported confidence in healthcare differed between the United Kingdom and the United States, as well as by rurality or urbanicity.

2) Key Messages

- We believe that while much current political and academic discourse surrounding healthcare is focused on systems, providers, and policy, patient experience and perception may also be key to understanding and responding to healthcare issues.
- Suburban residents in the US expressed higher confidence in both receiving effective treatment and affording care than their rural and urban counterparts; however, overall confidence in the US was significantly lower than in the UK, where residence type did not have an effect.
- These findings warrant examination of the causes for relative confidence levels in both regions, as well as among residence types within the US. Suburban healthcare in the US should be further examined to identify why it is associated with higher patient confidence levels.

3) Strengths and Limitations

Strengths:

- Confidence can serve as a useful proxy for understanding patient attitudes and behaviors and has implications distinct from other more commonly discussed notions such as satisfaction or trust, in that confidence implies components of self-efficacy.
- This analysis contributes to an ongoing discourse about healthcare systems by calling attention to the role of patient perspectives in this conversation. Such data provide a potential gauge of public response to policies affecting healthcare.

Limitations:

- Confidence is a subjective concept, and interpretations of the concept of confidence in one group may not be generalizable to another for semantic, cultural, and situational reasons.
- Similarly, the definition of "rurality" is not fixed, especially when comparing rural areas across different countries.

ABSTRACT:

Objective: Confidence in healthcare may influence patients' utilization of healthcare resources and perceptions of healthcare quality. We sought to determine whether self-reported confidence in healthcare differed between the United Kingdom and the United States, as well as by rurality or urbanicity.

Design: A secondary analysis of a subset of survey questions regarding self-reported confidence in healthcare from the 2010 Commonwealth Fund International Health Policy Survey.

Setting: Telephone survey of participants from the United Kingdom and the United States.

Participants: Our final analysis included 1,511 UK residents (688 rural, 446 suburban, 372 urban) and 2,501 US residents (536 rural, 1,294 suburban, 671 urban).

Outcome measures: Questions assessed respondents' confidence in the effectiveness and affordability of treatment. We compared survey outcomes from these questions between, and within, the two regions and among, and within, residence types (rural, suburban, and urban).

Results: Significant differences were found in self-reported confidence in healthcare between the UK and US, among residence types, and between the two regions within residence types. Reported levels were higher in the UK. Within regions, significant differences by residence type were found for the US but not the UK. Within the US, suburban respondents had the highest self-reported confidence in healthcare.

Conclusions: Significant differences exist between the UK and US in confidence in healthcare. In the US but not in the UK, self-reported confidence is related to residence type. Within countries, significant differences by residence type were found for the US but not the UK. Our findings warrant examination of causes for relative confidence levels between regions and among US residence types.

INTRODUCTION:

A focus on patient-centered care has emerged in recent years in discussions of health care delivery, systems of care, and direct care settings.[1, 2] Patient-centred care is typically defined as care that is responsive to individual patient needs and which facilitates shared decision making among patients, family members, and providers.[3] The patient experience is highly subjective and hinges on emotional, circumstantial, and interpretive factors that are difficult to quantify and compare across groups.

While patient satisfaction has been discussed at some length [4, 5], another subjective measure, the concept of patient confidence in health care, is one that has been understudied thus far. The question of provider confidence in patients' abilities to care for themselves has been studied, but this research did not look into patients' own confidence regarding their health and health care.[6] A survey conducted in the United States (US) explored the public's confidence in affording and accessing care.[7] Another US survey measured respondents' confidence in their ability to overcome disease without medical assistance.[8]

Related issues like patient satisfaction and self-efficacy have been explored in depth,[4, 5, 9, 10] but these notions are distinct from confidence. Confidence is defined as assurance or reliance on oneself, on other people or on things, or in circumstances.[11] Self-efficacy is related to personal sense of capacity/capability,[12] while satisfaction is a response or impression following an experience.[13] Consumer confidence in health care has been surveyed,[14] but this is a facet of confidence focused more narrowly on consumer spending. For the purposes of this paper, we draw on the dictionary definition[11] and previous health confidence survey questions[7] to define confidence in healthcare as a person's reliance on and trust in themselves and in their health system in yielding favorable health outcomes.

With the passage and implementation of the Patient Protection and Affordable Care Act in the US, discussions about healthcare have dominated recent political and popular discourse.[15, 16] While the focus often centers around fiscal, cultural, and ethical concerns, the tendency to criticize or praise a healthcare system may also be linked to biases, generalizations, and narratives based on personal experiences and beliefs.[17, 18] Confidence in one's individual health care and in the health system may play a key role in shaping patients' utilization, assessments, and stated desires regarding their health. Single-payer, publicly administered healthcare in the United Kingdom (UK) is often held up as a counterpoint to the more fragmented multi-payer, fee-for-service system in the US;[19, 20, 21] thus a comparison of patient confidence in these two regions could be helpful in better assessing the role of confidence in discussions and decisions pertaining to healthcare.

The UK has been found to have one of the highest levels of patient satisfaction among European countries,[22] and comparisons of health outcomes in the UK and US have explored physical and mental domains of health-related quality of life in the two regions.[23] US-based confidence surveys have explored perceptions and comprehension of health reform[7] and consumer confidence within the US.[14] Building on this research and on public interest in co-examining the UK and US systems, we see value in comparing the two regions on the subjective measure of confidence.

Some factors related to confidence in healthcare include patient satisfaction, medical skepticism, trust in government, health literacy, and management and organization of the healthcare system.[23-26] The efficiency and effectiveness of a healthcare system from a patient's perspective might affect patient adherence to medical therapies, self-efficacy, and determination to improve personal health.[27] In the case of medical skepticism, mistrust in the healthcare system could result in a patient's complete denial of any sort of service, believing that she or he is capable of taking care of their own health with no assistance.[23] Personal characteristics that have been found to influence confidence in personal health management are disease status, age, insurance coverage/ability to pay, the present health service infrastructure, language and cultural barriers, ethnicity, sex/gender, employment status, and socioeconomic position.[8] These factors may affect a health system's delivery of programs and services if community members do not feel confident in the system's ability to address issues specific to their community. Rural, lower resource communities with poorer system performance have been associated with low patient satisfaction,[28] and a Canadian study found that place of residence contributed to patient satisfaction.[29] Factors such as perceived or actual facility or system performance and residence type may influence patient confidence in healthcare.

We sought to determine whether self-reported confidence in healthcare differed between the United Kingdom and the United States, as well as by rurality or urbanicity.

METHODS:

Between March and June of 2010, the Commonwealth Fund's International Health Policy Survey was conducted via telephone surveys in 11 countries and from which we used data from the United Kingdom and the United States.[30] The survey contained questions about health and health care experiences, perceptions, coverage, and costs. Households in both the UK and the US were selected using random digit dialing, and both samples were drawn to be representative of the geographic population distribution in each country or region.[30] Alaska and Hawaii were excluded from the US survey. Collection methods are further described elsewhere.[30]

For this analysis, residence categorization data from the UK was recoded from four categories into three categories for side-by-side comparison with the US. American respondents were categorized as living in either a rural, suburban, or urban area. UK respondents were originally categorized as living in a village/rural area, a small town, a large town or suburb of a city, or an urban area. Village/rural area and small town were combined into one "rural" group.

Three questions in the survey sought to assess participants' confidence levels. These questions were: 1. "How confident are you that if you become seriously ill, you will receive the most effective treatment, including drugs and diagnostic tests?" 2. "How confident are you that if you become seriously ill, you will be able to afford the care you need?" and 3. How confident are you that you can control and manage your health problems?" Responses to all three questions were measured on a six-item Likert scale with the items "very confident," "confident," "not very confident," "not at all confident," "unsure," and "decline to answer."

Pearson's chi-square tests were used to compare relative frequencies between and within regions and between and within residence types. To compare data ordinally, rank sum tests were also conducted. Mann-Whitney U tests measured differences between the UK and US overall, as well as between the UK and US within each residence type. Kruskal-Wallis tests were used for rank-

sum comparisons between residence types overall and between residence types within each region or country. Significance was set at $p \leq 0.05$. All statistical analyses were conducted using Stata, Version 12 (StataCorp. 2011. Stata Statistical Software: Release 12. College Station, TX: StataCorp LP).

RESULTS:

Participants:

One thousand, five hundred and eleven (1,511) UK residents and 2,501 US residents responded to the survey. The UK response rate was 24%, and the US response rate was 26%.[16] Eighty-seven percent (86.8%) of UK and 77.0% of US respondents identified as white. Women made up 48.4% of the UK sample and 61.7% of the US respondents. Forty-six percent (45.5%) of UK respondents lived in rural areas or small towns. Only 21.4% of US respondents identified their residence as rural, while over half (51.7%) lived in suburban areas. Demographics are described further in Table 1. Data was missing for five UK respondents on residence type, so these five participants were excluded from the data analysis.

Table 1. Demographic Characteristics, by Region/Country of Residence and Residence Type

[a]Missing data from 5 UK respondents on Residence Type

[b]Missing data from 141 UK and 232 US respondents on Income Level

Outcomes:

A limited sample of respondents from each country (n=471 UK and 1,486 US) answered the question "How confident are you that you can control and manage your health problems?" Over 90% of this limited pool of respondents in both regions answered "very confident" or "confident," so a statistical comparison was not meaningful, and that question was removed from the final analysis. Results of the other two confidence questions, "How confident are you that if you become seriously ill, you will receive the most effective treatment, including drugs and diagnostic tests?" and "How confident are you that if you become seriously ill, you will be able to afford the care you need?" are described as follows.

Confidence in receiving effective treatment:

Overall, the differences between the UK and the US for responses on confidence in receiving effective treatment were significant for both chi-square and Mann-Whitney U tests (Table 2).

Table 2. Survey responses to the question:

How confident are you that if you become seriously ill, you will receive the most effective treatment, including drugs and diagnostic tests?

	Confidence Level (%)								
	Very confident	Confident	Not very confident	Not at all confident	Not sure	Decline to answer	χ^2	Mann-Whitney U	Kruskal-Wallis
Comparison between Region/Country[a]							p<0.001*	p<0.001*	
United Kingdom	32.0%	61.3%	5.6%	0.7%	0.4%	0.0%			
United States	34.6%	38.7%	16.0%	9.1%	1.3%	0.3%			
Comparison between Residence Types[b]							p=0.004*		p=0.004*
Rural	32.0%	51.2%	10.2%	5.2%	1.2%	0.1%			
Suburban	35.9%	44.9%	12.4%	5.6%	1.0%	0.2%

United Kingdom							p=0.817		p=0.781

United States	p=0.003*	p=0.001*

[a,c]Chi-square and Mann-Whitney U tests

[b,d]Chi-square and Kruskal-Wallis tests

Ninety-three percent (93.3%) of UK residents were confident or very confident in receiving effective treatment, compared with 73.3% of US residents. Within residence types, Mann-Whitney and chi-square tests revealed statistically significant differences between countries (all p<0.01). Among residence types overall, differences were also significant based on both chi-square and Kruskal-Wallis tests. Within each country, there were only statistically significant differences by residence type in the US (χ 2 p=0.003, Kruskal-Wallis p=0.001) and not in the UK (χ 2 p=0.817, Kruskal-Wallis p=0.781).

Confidence in affording care:
Statistically significant differences were found between the UK and US via chi-square and Mann-Whitney tests (Table 3).

Table 3. Survey responses to the question:
How confident are you that if you become seriously ill, you will be able to afford the care you need?

	Confidence Level (%)								
	Very confident	Confident	Not very confident	Not at all confident	Not sure	Decline to answer	χ^2	Mann-Whitney U	Kruskal-Wallis

United States							p=0.001*		p=0.001*

[a,c]Chi-square and Mann-Whitney U tests

[b,d]Chi-square and Kruskal-Wallis tests

In the UK, 91% of respondents were confident or very confident in their ability to afford healthcare, versus 61.6% in the US. Within residence types there were also statistically significant differences. Among residence types overall, there were only statistically significant differences based the chi-square test, not on the Kruskal-Wallis. Within the UK and US, as for the effective treatment question, differences in confidence based on residence type were only

statistically significant for US respondents (US: $\chi 2$ p=0.001, Kruskal-Wallis p=0.001; UK $\chi 2$ p=0.339, Kruskal-Wallis p=0.084).

A descriptive analysis of responses by residence type in the US revealed that suburban respondents had the highest percentage (76.3%) of confident or very confident ratings in effectiveness of treatment, versus 69.4% in rural areas and 70.4% in urban areas. Regarding ability to afford treatment in the US, 65.4% of suburban residents were confident or very confident, compared with 56.8% in rural areas and 58.2% in urban areas.

DISCUSSION:

Significant differences were found between the UK and the US in health confidence. Suburban residents in the US expressed higher confidence in both receiving effective treatment and affording care than their rural and urban counterparts; however, overall confidence in the US was significantly lower than in the UK, where residence type did not have an effect. The effect of the overall difference between residence types may be moderated by the lack of difference in the UK. Our findings are supported by a previous study which found that in the UK the public is happier than in the US (and other countries surveyed) regarding their healthcare system and are least likely to be worried about future health care needs.[31] Higher confidence in healthcare in the UK than in the US may be related to differences between healthcare systems, to cultural and political differences, or to differing social norms that may influence interpretations in answering questions about confidence. Examining causes for higher or lower respondent confidence could illuminate future directions for health system decision makers in both regions.

In addition to exploring the causes for relative confidence levels in regions, these findings also warrant closer examination of the different confidence levels among residence types within the US. Lower confidence in the rural US may not be simply attributable to health insurance coverage, as rural US coverage is highly variable.[32] Other factors such as income, race/ethnicity, age, and socio-cultural factors may combine to influence rural confidence.[32] The larger percentage of suburban Americans who rated their confidence as high implies that factors in the suburban environment may contribute to a sense of control or reliability. While disparities in access, safety, and quality of care between rural and urban areas are well-documented,[33, 34] our findings suggest that exploring the suburban healthcare environment could provide insight into US healthcare attitudes, especially given that 50% of Americans live in suburban areas.[35] Studies have explored rural, suburban, and urban localities as factors in health information management,[36] minority access to care,[37] and telemedicine satisfaction[38] with varying results for each measure. More targeted research on place of residence in health care confidence and quality may be advisable.

This analysis contributes to an ongoing discourse about the advantages and disadvantages of UK and US healthcare systems by calling attention to the role of patient perspectives in this conversation. How end users perceive their system to be serving them or accessible to them is an important factor in assessing, maintaining, and revising healthcare legislation, pricing, standards of care, and communication frameworks. Data on confidence, particularly in patient assessments of future or hypothetical health circumstances, provide insight into how patients might make decisions in planning and paying for health care. Such data also provide a potential gauge of public response to policies affecting healthcare. Our findings that UK residents have greater self-

reported confidence in healthcare might suggest higher levels of perceived reliability and system stability in their single-payer system as well as a perspective of confidence as a social norm. The outcomes determined here may be viewed not only as markers of patients' personal experiences with health care, but also as indicators of the sociocultural context in which each healthcare system functions. Comparing responses to confidence questions with responses about insurance status, accessibility of care, and personal factors such as income and age could be an area for follow up research that could clarify the extent to which expressions of confidence might be associated with system features versus other factors.

We acknowledge the inability to assess wholly the concept of confidence. Confidence in one group may not be generalizable to another for semantic, cultural, and situational reasons. However, confidence can serve as a useful proxy for understanding patient attitudes and behaviors and has implications distinct from other more commonly discussed notions such as satisfaction or trust, in that confidence implies components of self-efficacy. For both populations sampled in this study, data was gathered from English-speaking respondents who answered survey questions about confidence written in English, and both groups received the questions worded identically, providing some consistency in how confidence might be interpreted here across groups.

There remain a number of constraints and limitations on our data and subsequent conclusions which must be taken into consideration. The issue of confidence itself is somewhat troublesome given its inherently subjective nature and the myriad factors that can contribute to individual confidence. Age, gender, ethnicity, education, socioeconomic status, health status, and health literacy are just a few of the many factors that can potentially contribute to confidence in healthcare, and each might also serve as a potential confounder. Notably, two of the three Commonwealth Fund questions involve notions of personal forecasting ("if I become seriously ill, then..."), which may be more subject to biases than questions about conditions that are already present.

The definition of "rurality" can be problematic, especially given the disparate categories for the UK and US. Although the recoding of these categories to combine "village/ rural area" and "small town' in the UK was rather simple, definitions of what constitutes rural, suburban, and other descriptors varies culturally and contextually. It is also notable that four healthcare systems are included in the Commonwealth Fund's category for the UK. Scotland, Wales, Northern Ireland, and England each maintain unique healthcare systems, and despite their similarities, distinctions should be acknowledged when assigning value to UK health system effectiveness and quality in comparison with the US. For example, while universal registration for primary care is consistent across the four countries' health systems, there are key differences in prescription charges from country to country and in how each country is implementing recent reforms.[39] In addition to considering these distinct countries in future comparisons, other health care systems such as Canada's, which combines public funding with private sector delivery[40], could provide a useful point of comparison for future analyses of confidence in health care.

CONCLUSION:

Our analyses revealed significant differences between the UK and the US in self-reported

confidence levels, suggesting a disparity between these regions and their systems in the provision of equitable healthcare to all residents. Suburban healthcare in the US should be further examined to identify why it is associated with higher patient confidence levels. The findings of this study build on existing literature and may provide insight for policy developers and health practitioners working with rural, suburban, and urban communities. Patient confidence would be an interesting and culturally relevant measure for future survey projects to explore in more detail.

ACKNOWLEDGEMENTS:

ARTICLE SUMMARY

1) Article Focus

- This paper compares consumers' self-reported confidence in healthcare in the United Kingdom and the United States, using 2010 survey responses gathered by the Commonwealth Fund.
- We sought to determine whether self-reported confidence in healthcare differed between the United Kingdom and the United States, as well as by rurality or urbanicity.

2) Key Messages

- We believe that while much current political and academic discourse surrounding healthcare is focused on systems, providers, and policy, patient experience and perception may also be key to understanding and responding to healthcare issues.
- Suburban residents in the US expressed higher confidence in both receiving effective treatment and affording care than their rural and urban counterparts; however, overall confidence in the US was significantly lower than in the UK, where residence type did not have an effect.
- These findings warrant examination of the causes for relative confidence levels in both regions, as well as among residence types within the US. Suburban healthcare in the US should be further examined to identify why it is associated with higher patient confidence levels.

3) Strengths and Limitations

Strengths:

- Confidence can serve as a useful proxy for understanding patient attitudes and behaviours and has implications distinct from other more commonly discussed notions such as satisfaction, trust, and self-efficacy.
- This analysis contributes to an ongoing discourse about healthcare systems by calling attention to the role of patient perspectives in this conversation. Such data provide a potential gauge of public response to policies affecting healthcare.

Limitations:

- Confidence is a subjective concept, and interpretations of the concept of confidence in one group may not be generalizable to another for semantic, cultural, and situational reasons.
- Similarly, the definition of "rurality" is not fixed, especially when comparing rural areas across different countries.

ABSTRACT:

Objective: Confidence in healthcare may influence patients' utilization of healthcare resources and perceptions of healthcare quality. We sought to determine whether self-reported confidence in healthcare differed between the United Kingdom and the United States, as well as by rurality or urbanicity.

Design: A secondary analysis of a subset of survey questions regarding self-reported confidence in healthcare from the 2010 Commonwealth Fund International Health Policy Survey.

Setting: Telephone survey of participants from the United Kingdom and the United States.

Participants: Our final analysis included 1,511 UK residents (688 rural, 446 suburban, 372 urban) and 2,501 US residents (536 rural, 1,294 suburban, 671 urban).

Outcome measures: Questions assessed respondents' confidence in the effectiveness and affordability of treatment. We compared survey outcomes from these questions between, and within, the two regions and among, and within, residence types (rural, suburban, and urban).

Results: Significant differences were found in self-reported confidence in healthcare between the UK and US, among residence types, and between the two regions within residence types. Reported levels were higher in the UK. Within regions, significant differences by residence type were found for the US but not the UK. Within the US, suburban respondents had the highest self-reported confidence in healthcare.

Conclusions: Significant differences exist between the UK and US in confidence in healthcare. In the US, but not in the UK, self-reported confidence is related to residence type. Within countries, significant differences by residence type were found for the US but not the UK. Our findings warrant examination of causes for relative confidence levels between regions and among US residence types.

INTRODUCTION:

A focus on patient-centered care has emerged in recent years in discussions of healthcare delivery, systems of care, and direct care settings.[1, 2] Patient-centered care is typically defined as care that is responsive to individual patient needs and which facilitates shared decision making among patients, family members, and providers.[3] The patient experience is highly subjective and hinges on emotional, circumstantial, and interpretive factors that are difficult to quantify and compare across groups.

While patient satisfaction has been discussed at some length, [4, 5] another subjective measure, the concept of patient confidence in healthcare, is one that has been understudied thus far. The question of provider confidence in patients' abilities to care for themselves has been studied, but this research did not look into patients' own confidence regarding their health and healthcare.[6] A survey conducted in the United States (US) explored the public's confidence in affording and accessing care.[7] Another US survey measured respondents' confidence in their ability to overcome disease without medical assistance.[8] Consumer confidence in healthcare has been surveyed,[9] but this is a facet of confidence focused more narrowly on consumer spending.

Related issues like patient satisfaction and self-efficacy have been explored in depth,[4, 5, 10, 11] but these notions are distinct from confidence. Albert Bandura, who posited the widely held theory of self-efficacy as contributing to behaviours,[12] describes confidence as less conceptual than self-efficacy; confidence is a more generalized "strength of belief" but without the specificity to agency and capacity implied by self-efficacy.[13] Confidence has also been described as one component, along with skills and knowledge, that is necessary for a patient to be "activated" to participate in self-care or to make decisions with healthcare providers.[14] Self-efficacy is related to personal sense of capacity/capability, while satisfaction is a response or impression following an experience.[15]

With the passage and implementation of the Patient Protection and Affordable Care Act in the US, discussions about healthcare have dominated recent political and popular discourse.[16, 17] While the focus often centers around fiscal, cultural, and ethical concerns, the tendency to criticize or praise a healthcare system may also be linked to biases, generalizations, and narratives based on personal experiences and beliefs.[18, 19] Confidence in one's individual healthcare and in the health system may play a key role in shaping patients' utilization, assessments, and stated desires regarding their health. Single-payer, publicly administered healthcare in the United Kingdom (UK) is often held up as a counterpoint to the more fragmented multi-payer, fee-for-service system in the US;[20-22] thus a comparison of patient confidence in these two regions could be helpful in better assessing the role of confidence in discussions and decisions pertaining to healthcare.

The UK has been found to have one of the highest levels of patient satisfaction among European countries,[23] and comparisons of health outcomes in the UK and US have explored physical and mental domains of health-related quality of life in the two regions.[24] US-based confidence surveys have explored perceptions and comprehension of health reform[7] and consumer confidence within the US.[15] Building on this research and on public interest in co-examining the UK and US systems, we see value in comparing the two regions on the subjective measure of confidence.

Some factors related to confidence in healthcare include patient satisfaction, medical skepticism, trust in government, health literacy, and management and organization of the healthcare system.[24-27] The efficiency and effectiveness of a healthcare system from a patient's perspective might affect patient adherence to medical therapies, self-efficacy, and determination to improve personal health.[28] In the case of medical skepticism, mistrust in the healthcare system could result in a patient's complete denial of any sort of service, believing that she or he is capable of taking care of their own health with no assistance.[24] Personal characteristics that have been found to influence confidence in personal health management are disease status, age, insurance coverage/ability to pay, the present health service infrastructure, language and cultural barriers, ethnicity, sex/gender, employment status, and socioeconomic position.[8] These factors may affect a health system's delivery of programs and services if community members do not feel confident in the system's ability to address issues specific to their community. Rural, lower resource communities with poorer system performance have been associated with low patient satisfaction,[29] and a Canadian study found that place of residence contributed to patient satisfaction.[30] Factors such as perceived or actual facility or system performance and residence type may influence patient confidence in healthcare.

We sought to determine whether self-reported confidence in healthcare differed between the United Kingdom and the United States, as well as by rurality or urbanicity.

METHODS:

Between March and June of 2010, the Commonwealth Fund's International Health Policy Survey was conducted via telephone surveys in 11 countries and from which we used data from the United Kingdom and the United States.[31] The survey was conducted by Harris Interactive Inc. for the Commonwealth Fund. The survey contained questions about health and healthcare experiences, perceptions, coverage, and costs. Households in both the UK and the US were selected using random digit dialing, and both samples were drawn to be representative of the geographic population distribution in each country or region.[31] Alaska and Hawaii were excluded from the US survey. For the UK, interviewing took place throughout the UK (i.e., England, Scotland, Wales, and Northern Ireland). In both countries, respondent selection within the household was random, based on the "most recent birthday" method. In the UK, a web-based computer assisted telephone interviewing (web-based CATI) was used, while in the US, traditional CATI was used. Both forms of CATI are essentially the same, except that the web-based CATI program can be run off of Harris Interactive's own centrally-located server. In the UK, the surveys were conducted in English and averaged 20 minutes in length, while for the US, the surveys were conducted in English and Spanish and averaged 18 minutes in length. In both countries, professional interviewing staff conducted the interviewing and quality was continuously monitored by the supervisory staff. Collection methods are further described elsewhere.[31] The Commonwealth Fund granted permission for secondary analysis of this dataset.

For this analysis, residence categorization data from the UK was recoded from four categories into three categories for side-by-side comparison with the US. American respondents were categorized as living in either a rural, suburban, or urban area. UK respondents were originally categorized as living in a village/rural area, a small town, a large town or suburb of a city, or an urban area. Village/rural area and small town were combined into one "rural" group.

Three questions in the survey sought to assess participants' confidence levels. These questions were: 1. "How confident are you that if you become seriously ill, you will receive the most effective treatment, including drugs and diagnostic tests?" 2. "How confident are you that if you become seriously ill, you will be able to afford the care you need?" and 3. How confident are you that you can control and manage your health problems?" Responses to all three questions were measured on a six-item Likert scale with the items "very confident," "confident," "not very confident," "not at all confident," "unsure," and "decline to answer."

Pearson's chi-square tests were used to compare relative frequencies between and within regions and between and within residence types. To compare data ordinally, rank sum tests were also conducted. Mann-Whitney U tests measured differences between the UK and US overall, as well as between the UK and US within each residence type. Kruskal-Wallis tests were used for rank-sum comparisons between residence types overall and between residence types within each region or country. Significance was set at $p \leq 0.05$. All statistical analyses were conducted using Stata, Version 12 (StataCorp. 2011. Stata Statistical Software: Release 12. College Station, TX: StataCorp LP).

RESULTS:

Participants:

One thousand, five hundred and eleven (1,511) UK residents and 2,501 US residents responded to the survey. The UK response rate was 24%, and the US response rate was 26%.[16] Eighty-seven percent (86.8%) of UK and 77.0% of US respondents identified as white. Women made up 48.4% of the UK sample and 61.7% of the US respondents. Forty-six percent (45.5%) of UK respondents lived in rural areas or small towns. Only 21.4% of US respondents identified their residence as rural, while over half (51.7%) lived in suburban areas. Demographics are described further in Table 1. Data was missing for five UK respondents on residence type, so these five participants were excluded from the data analysis.

Table 1. Demographic Characteristics, by Region/Country of Residence and Residence Type

[a]Missing data from 5 UK respondents on Residence Type

[b]Missing data from 141 UK and 232 US respondents on Income Level

Outcomes:

A limited sample of respondents from each country (n=471 UK and 1,486 US) answered the question "How confident are you that you can control and manage your health problems?" Over 90% of this limited pool of respondents in both regions answered "very confident" or "confident," so a statistical comparison was not meaningful, and that question was removed from the final analysis. Results of the other two confidence questions, "How confident are you that if you become seriously ill, you will receive the most effective treatment, including drugs and diagnostic tests?" and "How confident are you that if you become seriously ill, you will be able to afford the care you need?" are described as follows.

Confidence in receiving effective treatment:

Overall, the differences between the UK and the US for responses on confidence in receiving effective treatment were significant for both chi-square and Mann-Whitney U tests (Table 2).

Table 2. Survey responses to the question:

How confident are you that if you become seriously ill, you will receive the most effective treatment, including drugs and diagnostic tests?

	Confidence Level (%)								
	Very confident	Confident	Not very confident	Not at all confident	Not sure	Decline to answer	χ^2	Mann-Whitney U	Kruskal-Wallis
Comparison between Region/Country[a]							p<0.001*	p<0.001*	
United Kingdom	32.0%	61.3%	5.6%	0.7%	0.4%	0.0%			
United States	34.6%	38.7%	16.0%	9.1%	1.3%	0.3%

[a,c]Chi-square and Mann-Whitney U tests

[b,d]Chi-square and Kruskal-Wallis tests

Ninety-three percent (93.3%) of UK residents were confident or very confident in receiving effective treatment, compared with 73.3% of US residents. Within residence types, Mann-Whitney and chi-square tests revealed statistically significant differences between countries (all p<0.01). Among residence types overall, differences were also significant based on both chi-square and Kruskal-Wallis tests. Within each country, there were only statistically significant differences by residence type in the US (χ 2 p=0.003, Kruskal-Wallis p=0.001) and not in the UK (χ 2 p=0.817, Kruskal-Wallis p=0.781).

Confidence in affording care:
Statistically significant differences were found between the UK and US via chi-square and Mann-Whitney tests (Table 3).

Table 3. Survey responses to the question:
How confident are you that if you become seriously ill, you will be able to afford the care you need?

	Confidence Level (%)								
	Very confident	Confident	Not very confident	Not at all confident	Not sure	Decline to answer	χ^2	Mann-Whitney U	Kruskal-Wallis
Comparison between Region/Country[a]							p<0.001*	p<0.001*	
United Kingdom	33.8%	57.2%	6.6%	0.6%	1.9%	0.0%			
United States	26.6%	35.0%	22.4%	13.6%	2.1%	0.3%			
Comparison between Residence Types[b]							p=0.002*		p=0.388

United States	p=0.001*	p=0.001*

[a,c]Chi-square and Mann-Whitney U tests

[b,d]Chi-square and Kruskal-Wallis tests

In the UK, 91% of respondents were confident or very confident in their ability to afford healthcare, versus 61.6% in the US. Within residence types there were also statistically significant differences. Among residence types overall, there were only statistically significant differences based the chi-square test, not on the Kruskal-Wallis. Within the UK and US, as for the effective treatment question, differences in confidence based on residence type were only statistically significant for US respondents (US: $\chi 2$ p=0.001, Kruskal-Wallis p=0.001; UK $\chi 2$ p=0.339, Kruskal-Wallis p=0.084).

A descriptive analysis of responses by residence type in the US revealed that suburban respondents had the highest percentage (76.3%) of confident or very confident ratings in effectiveness of treatment, versus 69.4% in rural areas and 70.4% in urban areas. Regarding ability to afford treatment in the US, 65.4% of suburban residents were confident or very confident, compared with 56.8% in rural areas and 58.2% in urban areas.

DISCUSSION:

Significant differences were found between the UK and the US in health confidence. Suburban residents in the US expressed higher confidence in both receiving effective treatment and affording care than their rural and urban counterparts; however, overall confidence in the US was significantly lower than in the UK, where residence type did not have an effect. The effect of the overall difference between residence types may be moderated by the lack of difference in the UK. Our findings are supported by a previous study which found that in the UK the public is happier than in the US (and other countries surveyed) regarding their healthcare system and are least likely to be worried about future healthcare needs.[32] Higher confidence in healthcare in the UK than in the US may be related to differences between healthcare systems, to cultural and political differences, or to differing social norms that may influence interpretations in answering questions about confidence. Examining causes for higher or lower respondent confidence could illuminate future directions for health system decision makers in both regions.

In addition to exploring the causes for relative confidence levels in regions, these findings also warrant closer examination of the different confidence levels among residence types within the US. Lower confidence in the rural US may not be simply attributable to health insurance coverage, as rural US coverage is highly variable.[33] Other factors such as income, race/ethnicity, age, and socio-cultural factors may combine to influence rural confidence.[33] The larger percentage of suburban Americans who rated their confidence as high implies that factors in the suburban environment may contribute to a sense of control or reliability. While disparities in access, safety, and quality of care between rural and urban areas are well-documented,[34, 35] our findings suggest that exploring the suburban healthcare environment could provide insight into US healthcare attitudes, especially given that 50% of Americans live in suburban areas.[36] Studies have explored rural, suburban, and urban localities as factors in health information management,[37] minority access to care,[38] and telemedicine satisfaction[39] with varying results for each measure. More targeted research on place of residence in healthcare confidence and quality may be advisable.

This analysis contributes to an ongoing discourse about the advantages and disadvantages of UK and US healthcare systems by calling attention to the role of patient perspectives in this conversation. How end users perceive their system to be serving them or accessible to them is an important factor in assessing, maintaining, and revising healthcare legislation, pricing, standards of care, and communication frameworks. Data on confidence, particularly in patient assessments of future or hypothetical health circumstances, provide insight into how patients might make decisions in planning and paying for healthcare. Such data also provide a potential gauge of public response to policies affecting healthcare. Our findings that UK residents have greater self-reported confidence in healthcare might suggest higher levels of perceived reliability and system stability in their single-payer system as well as a perspective of confidence as a social norm. The outcomes determined here may be viewed not only as markers of patients' personal experiences with healthcare, but also as indicators of the sociocultural context in which each healthcare system functions. Comparing responses to confidence questions with responses about insurance status, accessibility of care, and personal factors such as income and age could be an area for follow up research that could clarify the extent to which expressions of confidence might be associated with system features versus other factors.

There remain constraints and limitations on our data and subsequent conclusions that must be taken into consideration. We were limited by the variables available in a secondary dataset, and our use of secondary data was driven by empirical research questions rather than by a conceptual framework. This analysis of two countries is exploratory in nature, and further research would be needed to determine if our findings hold true in other countries.

We acknowledge the inability to assess wholly the concept of confidence. Bandura refers to confidence as nonspecific and a "catchword."[13] Confidence in one group may not be generalizable to another for semantic, cultural, and situational reasons. However, confidence is probably a more accessible term than "self-efficacy" or similar concepts for members of the public. As such, confidence may serve as a useful proxy in attempts to measure and understand patient attitudes and behaviours and has implications distinct from other commonly discussed notions such as satisfaction or trust, in that confidence implies components of self-efficacy. One study of diabetic patients in the US found a strong correlation between patient self-efficacy and confidence in health outcomes, underscoring these separately measured variables as related but distinct.[40] For both populations sampled in this study, data was gathered from primarily English-speaking respondents who answered survey questions about confidence originally written in English, and both groups received the questions worded identically, providing some consistency in how confidence might be interpreted here across groups.

The issue of confidence itself is somewhat unwieldy given the inherently subjective nature of the concept and the myriad factors that can contribute to individual confidence. Age, gender, ethnicity, education, socioeconomic status, health status, and health literacy are just a few of the many factors that can potentially contribute to confidence in healthcare, and each might also serve as a potential confounder. Notably, two of the three Commonwealth Fund questions involve notions of personal forecasting ("if I become seriously ill, then..."), which may be more subject to biases than questions about conditions that are already present.

The definition of "rurality" can be problematic, especially given the disparate categories for the UK and US. Although the recoding of these categories to combine "village/ rural area" and "small town' in the UK was rather simple, definitions of what constitutes rural, suburban, and other descriptors varies culturally and contextually. It is also notable that four healthcare systems are included in the Commonwealth Fund's category for the UK. Scotland, Wales, Northern Ireland, and England each maintain unique healthcare systems, and despite their similarities, distinctions should be acknowledged when assigning value to UK health system effectiveness and quality in comparison with the US. For example, while universal registration for primary care is consistent across the four countries' health systems, there are key differences in prescription charges from country to country and in how each country is implementing recent reforms.[41] In addition to considering these distinct countries in future comparisons, other healthcare systems such as Canada's, which combines public funding with private sector delivery,[42] could provide a useful point of comparison for future analyses of confidence in healthcare.

CONCLUSION:
Our analyses revealed significant differences between the UK and the US in self-reported confidence levels, suggesting a disparity between these regions and their systems in the provision of equitable healthcare to all residents. Suburban healthcare in the US should be further examined to identify why it is associated with higher patient confidence levels. The findings of this study build on existing literature and may provide insight for policy developers and health practitioners working with rural, suburban, and urban communities. Patient confidence would be an interesting and culturally relevant measure for future survey projects to explore in more detail.

ACKNOWLEDGEMENTS:
The authors wish to thank Cathy Schoen, Michelle Doty, Robin Osborn, David Squires, and Kristof Stremikis from the Commonwealth Fund for providing the data set and input on the final draft of this manuscript.

COMPETING INTERESTS: None to declare.

FUNDING: None of the authors have an actual or potential financial or commercial conflict of interest with the information presented in this manuscript.

DATA SHARING: No additional data available.

STATEMENT OF ETHICS: Ethics approval was not required for this study. The Commonwealth Fund granted permission for secondary analysis of the dataset used.

CONTRIBUTORSHIP: KH, MC, JP, AW, and NM conceived the study design. KH managed and analysed the data. KH, MC, JP, and AW participated in data interpretation and drafting the article. KH and NM were involved in revisions. All authors approved the final version.

ARTICLE SUMMARY

1) Article Focus

- This paper compares consumers' self-reported confidence in healthcare in the United Kingdom and the United States, using 2010 survey responses gathered by the Commonwealth Fund.
- We sought to determine whether self-reported confidence in healthcare differed between the United Kingdom and the United States, as well as by rurality or urbanicity.

2) Key Messages

- We believe that while much current political and academic discourse surrounding healthcare is focused on systems, providers, and policy, patient experience and perception may also be key to understanding and responding to healthcare issues.
- Suburban residents in the US expressed higher confidence in both receiving effective treatment and affording care than their rural and urban counterparts; however, overall confidence in the US was significantly lower than in the UK, where residence type did not have an effect.
- These findings warrant examination of the causes for relative confidence levels in both regions, as well as among residence types within the US. Suburban healthcare in the US should be further examined to identify why it is associated with higher patient confidence levels.

3) Strengths and Limitations

Strengths:

- Confidence can serve as a useful proxy for understanding patient attitudes and behaviours and has implications distinct from other more commonly discussed notions such as satisfaction, trust, and self-efficacy.
- This analysis contributes to an ongoing discourse about healthcare systems by calling attention to the role of patient perspectives in this conversation. Such data provide a potential gauge of public response to policies affecting healthcare.

Limitations:

- Confidence is a subjective concept, and interpretations of the concept of confidence in one group may not be generalizable to another for semantic, cultural, and situational reasons.
- Similarly, the definition of "rurality" is not fixed, especially when comparing rural areas across different countries.

ABSTRACT:

Objective: Confidence in healthcare may influence patients' utilization of healthcare resources and perceptions of healthcare quality. We sought to determine whether self-reported confidence in healthcare differed between the United Kingdom and the United States, as well as by rurality or urbanicity.

Design: A secondary analysis of a subset of survey questions regarding self-reported confidence in healthcare from the 2010 Commonwealth Fund International Health Policy Survey.

Setting: Telephone survey of participants from the United Kingdom and the United States.

Participants: Our final analysis included 1,511 UK residents (688 rural, 446 suburban, 372 urban) and 2,501 US residents (536 rural, 1,294 suburban, 671 urban).

Outcome measures: Questions assessed respondents' confidence in the effectiveness and affordability of treatment. We compared survey outcomes from these questions between, and within, the two regions and among, and within, residence types (rural, suburban, and urban).

Results: Significant differences were found in self-reported confidence in healthcare between the UK and US, among residence types, and between the two regions within residence types. Reported levels were higher in the UK. Within regions, significant differences by residence type were found for the US but not the UK. Within the US, suburban respondents had the highest self-reported confidence in healthcare.

Conclusions: Significant differences exist between the UK and US in confidence in healthcare. In the US, but not in the UK, self-reported confidence is related to residence type. Within countries, significant differences by residence type were found for the US but not the UK. Our findings warrant examination of causes for relative confidence levels between regions and among US residence types.

INTRODUCTION:

A focus on patient-centered care has emerged in recent years in discussions of healthcare delivery, systems of care, and direct care settings.[1, 2] Patient-centered care is typically defined as care that is responsive to individual patient needs and which facilitates shared decision making among patients, family members, and providers.[3] The patient experience is highly subjective and hinges on emotional, circumstantial, and interpretive factors that are difficult to quantify and compare across groups.

While patient satisfaction has been discussed at some length, [4, 5] another subjective measure, the concept of patient confidence in healthcare, is one that has been understudied thus far. The question of provider confidence in patients' abilities to care for themselves has been studied, but this research did not look into patients' own confidence regarding their health and healthcare.[6] A survey conducted in the United States (US) explored the public's confidence in affording and accessing care.[7] Another US survey measured respondents' confidence in their ability to overcome disease without medical assistance.[8] Consumer confidence in healthcare has been surveyed,[9] but this is a facet of confidence focused more narrowly on consumer spending.

Related issues like patient satisfaction and self-efficacy have been explored in depth,[4, 5, 10, 11] but these notions are distinct from confidence. Albert Bandura, who posited the widely held theory of self-efficacy as contributing to behaviours,[12] describes confidence as less conceptual than self-efficacy; confidence is a more generalized "strength of belief" but without the specificity to agency and capacity implied by self-efficacy.[13] Confidence has also been described as one component, along with skills and knowledge, that is necessary for a patient to be "activated" to participate in self-care or to make decisions with healthcare providers.[14] Self-efficacy is related to personal sense of capacity/capability, while satisfaction is a response or impression following an experience.[15]

With the passage and implementation of the Patient Protection and Affordable Care Act in the US, discussions about healthcare have dominated recent political and popular discourse.[16, 17] While the focus often centers around fiscal, cultural, and ethical concerns, the tendency to criticize or praise a healthcare system may also be linked to biases, generalizations, and narratives based on personal experiences and beliefs.[18, 19] Confidence in one's individual healthcare and in the health system may play a key role in shaping patients' utilization, assessments, and stated desires regarding their health. Single-payer, publicly administered healthcare in the United Kingdom (UK) is often held up as a counterpoint to the more fragmented multi-payer, fee-for-service system in the US;[20-22] thus a comparison of patient confidence in these two regions could be helpful in better assessing the role of confidence in discussions and decisions pertaining to healthcare.

The UK has been found to have one of the highest levels of patient satisfaction among European countries,[23] and comparisons of health outcomes in the UK and US have explored physical and mental domains of health-related quality of life in the two regions.[24] US-based confidence surveys have explored perceptions and comprehension of health reform[7] and consumer confidence within the US.[15] Building on this research and on public interest in co-examining the UK and US systems, we see value in comparing the two regions on the subjective measure of confidence.

Some factors related to confidence in healthcare include patient satisfaction, medical skepticism, trust in government, health literacy, and management and organization of the healthcare system.[24-27] The efficiency and effectiveness of a healthcare system from a patient's perspective might affect patient adherence to medical therapies, self-efficacy, and determination to improve personal health.[28] In the case of medical skepticism, mistrust in the healthcare system could result in a patient's complete denial of any sort of service, believing that she or he is capable of taking care of their own health with no assistance.[24] Personal characteristics that have been found to influence confidence in personal health management are disease status, age, insurance coverage/ability to pay, the present health service infrastructure, language and cultural barriers, ethnicity, sex/gender, employment status, and socioeconomic position.[8] These factors may affect a health system's delivery of programs and services if community members do not feel confident in the system's ability to address issues specific to their community. Rural, lower resource communities with poorer system performance have been associated with low patient satisfaction,[29] and a Canadian study found that place of residence contributed to patient satisfaction.[30] Factors such as perceived or actual facility or system performance and residence type may influence patient confidence in healthcare.

We sought to determine whether self-reported confidence in healthcare differed between the United Kingdom and the United States, as well as by rurality or urbanicity.

METHODS:

Between March and June of 2010, the Commonwealth Fund's International Health Policy Survey was conducted via telephone surveys in 11 countries and from which we used data from the United Kingdom and the United States.[31] The survey was conducted by Harris Interactive Inc. for the Commonwealth Fund. The survey contained questions about health and healthcare experiences, perceptions, coverage, and costs. Households in both the UK and the US were selected using random digit dialing, and both samples were drawn to be representative of the geographic population distribution in each country or region.[31] Alaska and Hawaii were excluded from the US survey. For the UK, interviewing took place throughout the UK (i.e., England, Scotland, Wales, and Northern Ireland). In both countries, respondent selection within the household was random, based on the "most recent birthday" method. In the UK, a web-based computer assisted telephone interviewing (web-based CATI) was used, while in the US, traditional CATI was used. Both forms of CATI are essentially the same, except that the web-based CATI program can be run off of Harris Interactive's own centrally-located server. In the UK, the surveys were conducted in English and averaged 20 minutes in length, while for the US, the surveys were conducted in English and Spanish and averaged 18 minutes in length. In both countries, professional interviewing staff conducted the interviewing and quality was continuously monitored by the supervisory staff. Collection methods are further described elsewhere.[31] The Commonwealth Fund granted permission for secondary analysis of this dataset.

For this analysis, residence categorization data from the UK was recoded from four categories into three categories for side-by-side comparison with the US. American respondents were categorized as living in either a rural, suburban, or urban area. UK respondents were originally categorized as living in a village/rural area, a small town, a large town or suburb of a city, or an urban area. Village/rural area and small town were combined into one "rural" group.

Three questions in the survey sought to assess participants' confidence levels. These questions were: 1. "How confident are you that if you become seriously ill, you will receive the most effective treatment, including drugs and diagnostic tests?" 2. "How confident are you that if you become seriously ill, you will be able to afford the care you need?" and 3. How confident are you that you can control and manage your health problems?" Responses to all three questions were measured on a six-item Likert scale with the items "very confident," "confident," "not very confident," "not at all confident," "unsure," and "decline to answer."

Pearson's chi-square tests were used to compare relative frequencies between and within regions and between and within residence types. To compare data ordinally, rank sum tests were also conducted. Mann-Whitney U tests measured differences between the UK and US overall, as well as between the UK and US within each residence type. Kruskal-Wallis tests were used for rank-sum comparisons between residence types overall and between residence types within each region or country. Significance was set at $p \leq 0.05$. All statistical analyses were conducted using Stata, Version 12 (StataCorp. 2011. Stata Statistical Software: Release 12. College Station, TX: StataCorp LP).

RESULTS:

Participants:

One thousand, five hundred and eleven (1,511) UK residents and 2,501 US residents responded to the survey. The UK response rate was 24%, and the US response rate was 26%.[16] Eighty-seven percent (86.8%) of UK and 77.0% of US respondents identified as white. Women made up 48.4% of the UK sample and 61.7% of the US respondents. Forty-six percent (45.5%) of UK respondents lived in rural areas or small towns. Only 21.4% of US respondents identified their residence as rural, while over half (51.7%) lived in suburban areas. Demographics are described further in Table 1. Data was missing for five UK respondents on residence type, so these five participants were excluded from the data analysis.

[a]Missing data from 5 UK respondents on Residence Type

[b]Missing data from 141 UK and 232 US respondents on Income Level

Outcomes:

A limited sample of respondents from each country (n=471 UK and 1,486 US) answered the question "How confident are you that you can control and manage your health problems?" Over 90% of this limited pool of respondents in both regions answered "very confident" or "confident," so a statistical comparison was not meaningful, and that question was removed from the final analysis. Results of the other two confidence questions, "How confident are you that if you become seriously ill, you will receive the most effective treatment, including drugs and diagnostic tests?" and "How confident are you that if you become seriously ill, you will be able to afford the care you need?" are described as follows.

Confidence in receiving effective treatment:

Overall, the differences between the UK and the US for responses on confidence in receiving effective treatment were significant for both chi-square and Mann-Whitney U tests (Table 2).

Table 2. Survey responses to the question:

How confident are you that if you become seriously ill, you will receive the most effective treatment, including drugs and diagnostic tests?

	Confidence Level (%)								
	Very confident	Confident	Not very confident	Not at all confident	Not sure	Decline to answer	χ^2	Mann-Whitney U	Kruskal-Wallis
Comparison between Region/Country[a]							p<0.001*	p<0.001*	
United Kingdom	32.0%	61.3%	5.6%	0.7%	0.4%	0.0%			
United States	34.6%	38.7%	16.0%	9.1%	1.3%	0.3%			
Comparison between Residence Types[b]							p=0.004*		p=0.004*

Rural	32.0%	51.2%	10.2%	5.2%	1.2%	0.1%			
Suburban	35.9%	44.9%	12.4%	5.6%	1.0%	0.2%			
Urban	31.7%	46.3%	13.8%	7.2%	0.6%	0.4%			
Comparison within Residence Types, by Region/Country[c]

Urban							p<0.001*	p<0.001*	
Comparison within Region/Country, by Residence Types[d]									
United Kingdom							p=0.817		p=0.781
United States							p=0.003*		p=0.001*

[a,c]Chi-square and Mann-Whitney U tests

[b,d]Chi-square and Kruskal-Wallis tests

Ninety-three percent (93.3%) of UK residents were confident or very confident in receiving effective treatment, compared with 73.3% of US residents. Within residence types, Mann-Whitney and chi-square tests revealed statistically significant differences between countries (all p<0.01). Among residence types overall, differences were also significant based on both chi-square and Kruskal-Wallis tests. Within each country, there were only statistically significant differences by residence type in the US (χ 2 p=0.003, Kruskal-Wallis p=0.001) and not in the UK (χ 2 p=0.817, Kruskal-Wallis p=0.781).

Confidence in affording care:
Statistically significant differences were found between the UK and US via chi-square and Mann-Whitney tests (Table 3).

Table 3. Survey responses to the question:
How confident are you that if you become seriously ill, you will be able to afford the care you need?

	Confidence Level (%)								
	Very confident	Confident	Not very confident	Not at all confident	Not sure	Decline to answer	χ^2	Mann-Whitney U	Kruskal-Wallis
Comparison between Region/Country[a]							p<0.001*	p<0.001*	
United Kingdom	33.8%	57.2%	6.6%	0.6%	1.9%	0.0%

[a,c]Chi-square and Mann-Whitney U tests

[b,d]Chi-square and Kruskal-Wallis tests

In the UK, 91% of respondents were confident or very confident in their ability to afford healthcare, versus 61.6% in the US. Within residence types there were also statistically significant differences. Among residence types overall, there were only statistically significant differences based the chi-square test, not on the Kruskal-Wallis. Within the UK and US, as for the effective treatment question, differences in confidence based on residence type were only statistically significant for US respondents (US: $\chi 2$ p=0.001, Kruskal-Wallis p=0.001; UK $\chi 2$ p=0.339, Kruskal-Wallis p=0.084).

A descriptive analysis of responses by residence type in the US revealed that suburban respondents had the highest percentage (76.3%) of confident or very confident ratings in effectiveness of treatment, versus 69.4% in rural areas and 70.4% in urban areas. Regarding ability to afford treatment in the US, 65.4% of suburban residents were confident or very confident, compared with 56.8% in rural areas and 58.2% in urban areas.

DISCUSSION:

Significant differences were found between the UK and the US in health confidence. Suburban residents in the US expressed higher confidence in both receiving effective treatment and affording care than their rural and urban counterparts; however, overall confidence in the US was significantly lower than in the UK, where residence type did not have an effect. The effect of the overall difference between residence types may be moderated by the lack of difference in the UK. Our findings are supported by a previous study which found that in the UK the public is happier than in the US (and other countries surveyed) regarding their healthcare system and are least likely to be worried about future healthcare needs.[32] Higher confidence in healthcare in the UK than in the US may be related to differences between healthcare systems, to cultural and political differences, or to differing social norms that may influence interpretations in answering questions about confidence. Examining causes for higher or lower respondent confidence could illuminate future directions for health system decision makers in both regions.

In addition to exploring the causes for relative confidence levels in regions, these findings also warrant closer examination of the different confidence levels among residence types within the US. Lower confidence in the rural US may not be simply attributable to health insurance coverage, as rural US coverage is highly variable.[33] Other factors such as income, race/ethnicity, age, and socio-cultural factors may combine to influence rural confidence.[33] The larger percentage of suburban Americans who rated their confidence as high implies that factors in the suburban environment may contribute to a sense of control or reliability. While disparities in access, safety, and quality of care between rural and urban areas are well-documented,[34, 35] our findings suggest that exploring the suburban healthcare environment could provide insight into US healthcare attitudes, especially given that 50% of Americans live in suburban areas.[36] Studies have explored rural, suburban, and urban localities as factors in health information management,[37] minority access to care,[38] and telemedicine satisfaction[39] with varying results for each measure. More targeted research on place of residence in healthcare confidence and quality may be advisable.

This analysis contributes to an ongoing discourse about the advantages and disadvantages of UK and US healthcare systems by calling attention to the role of patient perspectives in this conversation. How end users perceive their system to be serving them or accessible to them is an important factor in assessing, maintaining, and revising healthcare legislation, pricing, standards of care, and communication frameworks. Data on confidence, particularly in patient assessments of future or hypothetical health circumstances, provide insight into how patients might make decisions in planning and paying for healthcare. Such data also provide a potential gauge of public response to policies affecting healthcare. Our findings that UK residents have greater self-reported confidence in healthcare might suggest higher levels of perceived reliability and system stability in their single-payer system as well as a perspective of confidence as a social norm. The outcomes determined here may be viewed not only as markers of patients' personal experiences with healthcare, but also as indicators of the sociocultural context in which each healthcare system functions. Comparing responses to confidence questions with responses about insurance status, accessibility of care, and personal factors such as income and age could be an area for follow up research that could clarify the extent to which expressions of confidence might be associated with system features versus other factors.

There remain constraints and limitations on our data and subsequent conclusions that must be taken into consideration. We were limited by the variables available in a secondary dataset, and our use of secondary data was driven by empirical research questions rather than by a conceptual framework. This analysis of two countries is exploratory in nature, and further research would be needed to determine if our findings hold true in other countries.

We acknowledge the inability to assess wholly the concept of confidence. Bandura refers to confidence as nonspecific and a "catchword."[13] Confidence in one group may not be generalizable to another for semantic, cultural, and situational reasons. However, confidence is probably a more accessible term than "self-efficacy" or similar concepts for members of the public. As such, confidence may serve as a useful proxy in attempts to measure and understand patient attitudes and behaviours and has implications distinct from other commonly discussed notions such as satisfaction or trust, in that confidence implies components of self-efficacy. One study of diabetic patients in the US found a strong correlation between patient self-efficacy and confidence in health outcomes, underscoring these separately measured variables as related but distinct.[40] For both populations sampled in this study, data was gathered from primarily English-speaking respondents who answered survey questions about confidence originally written in English, and both groups received the questions worded identically, providing some consistency in how confidence might be interpreted here across groups.

The issue of confidence itself is somewhat unwieldy given the inherently subjective nature of the concept and the myriad factors that can contribute to individual confidence. Age, gender, ethnicity, education, socioeconomic status, health status, and health literacy are just a few of the many factors that can potentially contribute to confidence in healthcare, and each might also serve as a potential confounder. Notably, two of the three Commonwealth Fund questions involve notions of personal forecasting ("if I become seriously ill, then..."), which may be more subject to biases than questions about conditions that are already present.

The definition of "rurality" can be problematic, especially given the disparate categories for the UK and US. Although the recoding of these categories to combine "village/ rural area" and "small town' in the UK was rather simple, definitions of what constitutes rural, suburban, and other descriptors varies culturally and contextually. It is also notable that four healthcare systems are included in the Commonwealth Fund's category for the UK. Scotland, Wales, Northern Ireland, and England each maintain unique healthcare systems, and despite their similarities, distinctions should be acknowledged when assigning value to UK health system effectiveness and quality in comparison with the US. For example, while universal registration for primary care is consistent across the four countries' health systems, there are key differences in prescription charges from country to country and in how each country is implementing recent reforms.[41] In addition to considering these distinct countries in future comparisons, other healthcare systems such as Canada's, which combines public funding with private sector delivery,[42] could provide a useful point of comparison for future analyses of confidence in healthcare.

CONCLUSION:
Our analyses revealed significant differences between the UK and the US in self-reported confidence levels, suggesting a disparity between these regions and their systems in the provision of equitable healthcare to all residents. Suburban healthcare in the US should be further examined to identify why it is associated with higher patient confidence levels. The findings of this study build on existing literature and may provide insight for policy developers and health practitioners working with rural, suburban, and urban communities. Patient confidence would be an interesting and culturally relevant measure for future survey projects to explore in more detail.

ACKNOWLEDGEMENTS:
The authors wish to thank Cathy Schoen, Michelle Doty, Robin Osborn, David Squires, and Kristof Stremikis from the Commonwealth Fund for providing the data set and input on the final draft of this manuscript.

COMPETING INTERESTS: None to declare.

FUNDING: None of the authors have an actual or potential financial or commercial conflict of interest with the information presented in this manuscript.

DATA SHARING: There is no additional data available.

STATEMENT OF ETHICS: Ethics approval was not required for this study. The Commonwealth Fund granted permission for secondary analysis of the dataset used.
