Abstract

Objectives: To explore the experiences of patients and professionals taking part in a randomised controlled trial (RCT) of remote blood pressure (BP) telemonitoring supported by primary care. To identify factors facilitating or hindering the success of the intervention and those likely to influence its potential translation to routine practice.

Design: Qualitative study adopting a qualitative descriptive approach.

Participants: Twenty five patients, 11 nurses and 9 doctors who were participating in an RCT of BP telemonitoring. A maximum variation sample of patients based on age, sex, and deprivation status of the practice was sought.

Setting: Six primary care practices in Scotland.

Method: Data were collected via taped semi-structured interviews. Initial thematic analysis was inductive. Multiple strategies were employed to ensure that the analysis was credible and trustworthy.

Results: Prior to the trial both patients and professionals were reluctant to increase medication based on single BP measurements taken in the surgery. BP measurements based on multiple electronic readings were perceived as more accurate as a basis for action. Patients using telemonitoring became more engaged in the clinical management of their condition. Professionals reported that telemonitoring challenged existing roles and work practices and increased workload. Lack of integration of telemonitoring data with the electronic health record (EHR) was perceived as a drawback.

Conclusions: BP telemonitoring in a usual care setting can provide a trusted basis for medication management and improved BP control. It increases patients' engagement in the management of their condition, but supporting telemetry and greater patient engagement can increase professional workloads and demand changes in service organisation. Successful service design in practice would have to take account of how additional roles and responsibilities could be re-aligned with existing work and data management practices

The embedded qualitative study was included in the protocol for the HITS trial registered with ISRCTN no. 72614272.

Summary

Article Summary - **This should consist of three headings: 'Article focus' (up to three bullet points on the research questions or hypotheses addressed); 'Key messages' (up to three bullet points showing the key messages or significance of the study); and a 'Strengths and limitations of this study' section.**

Article Focus

- Qualitative exploration of the experiences of patients and professionals taking part in a randomised controlled trial (RCT) of remote blood pressure (BP) telemonitoring supported by primary care.
- Identification of factors facilitating or hindering the success of the intervention and those likely to influence its potential translation to routine practice

Key Messages

- BP telemonitoring in a usual care setting can provide a trusted basis for medication management and improved BP control.
- It increases patients' engagement in the management of their condition,
- Supporting telemonitoring and greater patient engagement can increase professional workloads and demand changes in service organisation.

Strengths and limitations of this study

The strengths of the study are that it is based on experience of using the systems by the patients' own practitioners in a usual care context. The trial context permitted triangulation with quantitative data. Because the protocol permitted evolution in practice, it gives an indication of some of the issues which would need to be addressed for BP telemonitoring to be used in routine practice. The weaknesses are that participation in the study was relatively short for each practice with limited patient numbers so any longer term barriers to evolution in practice were not identified. It is also possible that participants in this study differ from non-participants.

Background

Long term illness is increasingly prevalent and telemonitoring (remote self-monitoring of health parameters with electronic transmission of data to a health care provider) is considered to be a promising way of supporting patient care within existing resources.¹ However, despite policy statements and numerous pilots, telemonitoring has not yet been widely adopted.² This qualitative study examined patient and professional experiences of BP telemonitoring in the context of an RCT. As an embedded qualitative study its purpose was to help explain the trial results and to generate insights regarding factors likely to influence the adoption of this approach within routine care.

Hypertension (persistently raised BP >140/90 mmHg), is a major cardiovascular risk factor, which is frequently poorly controlled,³ with evidence of under treatment in many cases, sometimes described as 'therapeutic inertia'.⁴ This is despite the availability of guidelines^{5,6} or (as in the UK) financial incentives to primary care doctors.⁷ In day-to-day practice effective assessment of BP is problematic. Single BP measurements taken in the surgery are poorer indicators of risk than estimates based on multiple measures from ambulatory or home monitoring^{8,9,10} and 'white coat hypertension' – raised BP when measured in the surgery, but not at home¹¹ – is a complicating factor. However, for practical reasons, surgery-based measurements are still the basis of treatment decision making in most cases. Telemonitoring can overcome these measurement issues by allowing patients to take multiple BP readings at home and share them with healthcare professionals in almost real time, potentially providing motivation for improvements in self-care whilst facilitating professional input if necessary. Although we have been unable to identify previous qualitative studies of telemonitoring in hypertension in a usual care setting, some common themes are emerging from qualitative studies where the self-monitoring was either part of a larger intervention such as specialist nursing support or self-management of medication,^{12,13} or the patients were simply self-monitoring with no data transmission.^{14,15} The common themes were that patients generally find self-monitoring to be a positive experience which is empowering, reassuring and motivational.

The trial which formed the context for this study¹⁶ (see Box 1 for summary of the intervention) involved patients who had a BP higher than 135/85mmHg on daytime ambulatory BP monitoring and found that for those using telemonitoring, BP reduced by a mean of 4.3/ 2.6 mmHg compared with the group receiving usual care. Other trials in this field also strongly suggest that telemonitoring in hypertension can be effective in achieving clinically important reductions in systolic and diastolic BP^{17,18} but some studies have shown poorer outcomes.¹⁹ The introduction of telemonitoring may be regarded as a complex sociotechnical intervention involving changes in behaviour in addition to a purely technological solution. It is therefore important to understand how components of the

1 intervention and contextual factors contribute to the outcome.²⁰ These issues can be difficult to
2 explore using quantitative methods alone²¹ and proponents of 'realist evaluation' suggest using
3 qualitative methods to tease out what works in different contexts.²² The aim of this study, therefore,
4 was to qualitatively explore the experiences of patients and professionals taking part in a trial of BP
5 telemonitoring based in a usual care setting, to identify what contributed to the success of the
6 intervention, what limited its success and what may be required for the success of the trial to be
7 translated into routine care.

11
12

13 **Methods**

14 **Overview**

15 This study was embedded within an RCT of BP telemonitoring in routine care for patients whose BP
16 was above target¹⁶ (Box 1). Patients who had diabetes or previous stroke or transient ischaemic
17 attack were not included as they were asked to take part in separate trials. A qualitative descriptive
18 approach was employed,²³ acknowledging that in health services research the need of the
19 researcher is not simply to provide a description of the phenomenon, but also to produce an
20 interpretive account which will help to guide health care innovation whilst, at the same time,
21 recognising the subjective nature of the encounter between the subject and the researcher.²⁴

32

33 **Ethics and governance considerations**

34 The study received ethical approval from the South East Scotland Ethics Service (08/S1101/38) and
35 R&D approval from NHS Lothian. Patients were made aware that they may be approached for the
36 embedded qualitative study when they agreed to participate in the trial, but that participation in this
37 study would be optional. Patients and professionals approached were sent a separate information
38 sheet about the qualitative study and signed an additional consent prior to participation.
39
40
41
42
43
44

45 **Sampling and recruitment**

46 Twenty GP practices and 401 patients participated in the RCT. Of these, patients and staff from five
47 socio-economically diverse practices (based on the Scottish Index of Multiple Deprivation²⁵) were
48 initially approached to participate in the qualitative study. A sixth practice was added later to
49 increase the number of professionals participating and ensure data saturation. A maximum
50 variation patient sample of at least 20 patients overall from these practices was sought based on
51 age, sex, and the deprivation status of the practice. Patients participating in the trial were
52 purposively sampled and checks were made with the practice to ensure that it was still appropriate
53
54
55
56
57
58
59
60

1 to approach the patient before they were contacted by letter. Those who did not respond were
2 replaced by patients with similar characteristics. The aim of this sampling strategy was to capture a
3 broad range of patient experiences across the socio-economic spectrum included within the trial.
4
5
6
7
8

9 **Data generation and handling**

10 Qualitative data were gathered through semi-structured interviews with patients, nurses and
11 doctors. The initial topic guides were based on issues identified by our previous acceptability
12 study²⁶ and interviews with patients participating in the trial pilot study. The interview topic guides
13 were refined iteratively in response to the initial interviews. The final topic guides are shown in
14 Appendix 1. Most patients were interviewed face-to-face in their own home, and professionals at
15 their workplace, with interviews carried out by telephone where this was not possible. Most
16 healthcare professionals were interviewed individually, but two nurses were interviewed together,
17 as were three doctors. Interviews were carried out by JU, an experienced female qualitative
18 researcher with a background in education and psychology who was not involved in the RCT.

24
25
26
27
28

29 **Data handling and analysis**

30 All interviews were recorded, fully transcribed and the transcript checked against the recording.
31 They were analysed thematically with initial codes and themes identified inductively from the data.
32 Patient and professional data were coded separately. Coding was marked on the transcripts using
33 the comments facility in Microsoft Word and the text associated with each code stored on an Excel
34 spreadsheet. Initial coding took place after small groups of interviews and interviewing continued
35 until data saturation (no new themes arising) was achieved
36
37
38
39
40
41

42 A range of strategies was employed to ensure that the analysis was credible and trustworthy.
43 Constant comparison was used to ensure consistency in coding and negative cases were sought for
44 each coding category. Coding was checked and iteratively refined using paired analysis of transcripts
45 by two researchers. Researcher reflexivity was supported by discussing emerging findings with the
46 wider research group where different explanations were explored and the coding and thematic
47 analysis reviewed and refined. Following this, the thematic analysis was presented by JH to a
48 discussion group of 21 patients, professionals and researchers who had participated. The
49 presentation introduced the themes and illustrative quotes and the whole dataset (all the text
50 associated with each code) was made available to the participants. This discussion, which lasted for
51 90 minutes, was moderated by BM, recorded, transcribed and coded. It was used to validate the
52
53
54
55
56
57
58
59
60

1 initial grouping of data into codes and themes, but also to extend the discussion of how telehealth
2 may change the provision of primary care. The coding is shown in Appendix 2.

3
4
5 The themes were grouped into the four overarching themes presented here. The groupings were
6 broadly informed by the purpose of the study and also by the normalisation process model as
7 applied to telehealth, with its constructs of interactional workability, relational integration, skill set
8 workability and contextual integration²⁷. Appendix 2 shows the codes, (with the number of text
9 extracts coded against each), and how they have been grouped into themes and overarching
10 themes. Where it was possible to triangulate findings arising from the qualitative data against the
11 quantitative trial data (eg workload impacts), this was also done. Three overarching themes are
12 presented here. The fourth theme comprised comments about the study and is shown in Appendix
13 2.
14
15
16
17
18
19

20 21 22 Results

23
24 Thirty four patients were approached (28 from the intervention arm and eight from the control arm)
25 and 25 patients (5 from the control arm of the trial) participated. The patient characteristics are
26 shown in Table 1. Eleven practice nurses (all female) and 9 GPs (4 male, 5 female) took part.
27
28

29 The telemonitoring service employed in this study was novel in that self-monitoring was integrated
30 with usual care. For this reason we present the patient and professional data together here,
31 highlighting areas of concordance, divergence and evolution in practice both between and within the
32 professional and patient groups.
33
34
35

36 37 The Patient Experience

38
39 Patients' accounts of their response to the initial diagnosis of hypertension differed, as did their level
40 of concern and their personal approaches to self-management. Some were not concerned, did not
41 think of their hypertension often and left the management to their doctor or nurse. For others the
42 diagnosis had caused practical problems (e.g. in taking out life insurance) or anxiety, particularly
43 where they had experience of a family member suffering a stroke. Anxiety about what was
44 happening to their BP between appointments had led some to self-monitor their BP prior to this
45 study. Contrasting perspectives are illustrated in the quotations below.
46
47
48
49
50

51 *Oh I just take my tablet. I don't think about it.....I'm not the worrying kindI don't*
52 *see the point in worrying over things.* (Patient 1)
53
54
55
56
57
58
59
60

1 Some participants had modified their lifestyle prior to the trial in response to the diagnosis of
2 hypertension
3

4 *What I did do [when diagnosed with hypertension] and I've stuck to it, I've cut out salt. I was*
5 *overweight a few years ago and I cut out butter, so now I don't have butter and I don't have*
6 *salt. (I) just (use) general knowledge, just tried to reduce salt, reduce weight. And salt brings*
7 *up your blood pressure so...*
8
9 (Patient 12)

10
11
12
13
14 Some of the patients interviewed had modified their lifestyle during the trial, and considered that
15 the system provided motivation

16
17 *"... I had lost a stone in weight during the course of that six months as well that I was being*
18 *on the monitor and I think that did. I think that was a contributory factor to my BP balancing*
19 *out"*
20 (Patient 7)

21
22
23 *"When I was taking the blood pressure I couldn't bear looking at a hundred and forty, a*
24 *hundred and fifty over a hundred and ten and I wanted to just be able to see better readings*
25 *in a way. So over the summer as well, starting to get more walking exercise, that kind of*
26 *thing.... I didn't want beta blockers because they had various side effects which..... I kind of*
27 *felt the conventional medicine options were maybe a bit limited in terms of what I wanted*
28 *out of it or in terms of avoiding side effects, so it did spur me on to look for alternative..."*
29

30
31
32
33 (Patient 2)

34
35
36 *"So I like having the machine there because it prompts me, and I've done things like I've done*
37 *some exercise and then I've taken my blood pressure to see whether it has made an impact,*
38 *and it did, it does, every time."*
39

40
41 (Patient 20)

42
43
44
45 However, many others were aware of the need for lifestyle change but found it too difficult to
46 implement .
47

48
49 *"...obviously I'm overweight, I'm trying to do something about that but it just doesn't*
50 *happen".*
51 (Patient 4)

52
53
54
55
56 The quantitative results of the trial¹⁶ did not show any significant changes to lifestyle variables
57 relating to diet, exercise or medication adherence in either the intervention or control groups.
58
59
60

1 However, closer examination of the trial data did show that in both groups a small number of
2 individuals (10 overall) had, as described by Patient 7, lost more than 1 stone (6.5Kg) in weight.
3
4

5
6
7 Using the system increased some patients' engagement with the medical management of their
8 hypertension. They used it to negotiate treatment and, in a very small number of cases, titrate their
9 own medication.
10
11

12
13
14
15 *"It's certainly given me more meaningful data to speak to the doctor rather than, "Well, I
16 think my BP has probably gone up." "* (Patient 6)
17
18

19
20
21
22 *"...I've got 16 milligrams and eight milligrams [tablets of antihypertensive drug] and the last
23 time I saw Dr B he said; the maximum you can have is 32. Well what I probably could do is go
24 and see the nurse and say can I take it upon myself to move it up to 32 by taking another
25 eight"*
26
27

28
29 (Patient 19)
30

31 Generally, both patients and professionals thought the increased patient engagement in BP
32 management was beneficial.
33
34

35 *"Yes. I really thought that it (system)was a brilliant idea. And it has helped me a lot, to
36 understand more"* (Patient 4)
37
38

39
40
41
42 *"...the positive thing about it was it definitely helps patients to become much more involved
43 in their care which is a good thing and they definitely take much more interest in it I think
44 because they're measuring it, they can see it, you know it's much more real to them I think"*
45
46

47 (Practice Nurse 9)
48

49 However, a note of caution was sounded, again by both patients and professionals, that for a small
50 number of people home monitoring could provoke anxiety
51
52

53
54 *"I felt it was intrusive. I started worrying about my BP"* (Patient 12)
55
56

1 *"....and then you've got others; 'Oh, I feel a bit ill today, I'll better check my BP'... and I think*
2
3 *that that's the danger of home monitoring, I think people can become obsessed with it..."*

4 *(Practice Nurse 6)*

5
6
7 Although both patients and professionals raised the issue of anxiety generated by home monitoring,
8 it was a much stronger theme amongst the professionals. It was only raised by one patient during
9 the interviews, but several professionals. This accords with our previous telehealth work where
10 there is considerable concern amongst professional about the possibility of telehealth putting
11 patients in a 'sick role' and making them dependent or anxious, but this concern is not widely
12 echoed by patients^{28, 29}.

19 **Using the telemonitoring system**

20
21
22 The simple telemonitoring system used in this study generally worked well, although some design
23 issues were highlighted as described below. Generally, patients had little difficulty measuring their
24 BP, transmitting their readings or finding a routine for measuring their BP. Some also accessed the
25 on-line record of their readings. However, the wording of the automated feedback messages sent by
26 the system to was not found to be valuable although the messages in themselves did remind some
27 patients to maintain their engagement with the system.

28
29 *"it's the same message from presumably a machine [laughs] which doesn't help a lot.*
30 *Because it's obviously coming from a machine and it tells me have I contacted my medical*
31 *practice or nurse, which I have but it doesn't seem to know that, you see?" (Patient 9)*

32
33
34 The main clinical advantage provided by the system was that that it facilitated management of BP
35 using average BP, based on multiple readings taken at home, which was seen by both patients and
36 professionals as a more trustworthy basis for action than single BP measurements taken in the
37 surgery. Both patients and professionals commented that, prior to the system being introduced,
38 there were sometimes long delays in initiating appropriate treatment in people with less markedly
39 raised BP, driven by reluctance by healthcare staff to prescribe medication which may not be
40 absolutely necessary. The data from the patients who were not in the intervention group suggested
41 that, for them, medication changes remained infrequent and this was supported by the trial data¹⁶.

42
43 *"[prior to the trial]... you have a BP maybe 148 over 88, you might say 'let's see you again in*
44 *six months', when actually it's too high"*
45 *(Practice Nurse 10)*

1 The trial thus flagged wider implementation issues such as the need for reconfiguration of work
2 practices to accommodate new roles, and ensure synergies across a more distributed care team, as
3 well as more integrated access to patient data from disparate data sources.
4
5
6
7
8

9 **Adjusting to new responsibilities and new ways of working**

10 The new service and increased patient engagement challenged organisation within practices.
11 Professionals reported that monitoring the electronic data, increased patient contact and the need
12 for more rapid decision making raised workloads. The consensus was that a nurse-led service would
13 be the best model, but monitoring the system needed to be an acknowledged part of the practice
14 nurses' role with regular formal time set aside for an electronic clinic. Not all practices succeeded in
15 monitoring the electronic data regularly throughout the trial. The trial data confirmed the increased
16 workload with patients in the telemonitoring group having, on average, two additional consultations
17 with the practice (one with the GP and one with the practice nurse, half of which were by telephone)
18 over the 6 months of the trial compared to the control group.¹⁶
19
20
21
22
23
24
25

26 Care had traditionally been face- to- face, but continuing to use this model to try to respond quickly
27 to the telemetry data had its frustrations.
28
29
30

31 *"We would phone them and say your BP's up, we need to increase your medication or you*
32 *need to come in and see someone ... And they never made appointments and then we had to*
33 *phone them again and say 'You've still not made an appointment, are you coming in?'"*
34
35

36 *(Practice Nurse 3)*

37
38 Some professionals began to change how they worked, reducing reliance on face-to-face contact
39 with the patients. Telephone contact increased although it was also found to be a time consuming
40 way of reaching patients who were frequently not available during working hours.
41
42
43

44 *"I feel like I'm phoning these patients all the time. If they can't get them in and you're having*
45 *to leave a message then you're going to have to leave a message in the book to make sure*
46 *they've got the message. You're checking to see if they've picked up a prescription because*
47 *you're then checking their blood pressure - it's still high - 'Have they taken their medication?'*
48 *You're phoning them... "*
49
50
51

52 *(Practice nurse 4)*
53
54
55
56
57
58
59
60

1 There was some experimentation in using email with appropriate safeguards and, although only a
2 small number were involved, this worked well.
3

4
5 *"...I got an email from the doctor every week from the readings and he was able to advise me*
6 *without me having to visit the doctor.*
7

8
9 *(Researcher.... how did you feel about that?)*
10

11 *Well I was quite happy with that. I thought that was great. It was very time saving for me.*
12

13
14 *(Researcher: Ahah. So you find the time saving aspect then very useful?)*
15

16 *Oh, yes, yes definitely. No effort making appointments, you just got an automatic email*
17 *every week. They give suggestions and like "Take more of the tablets. Take less of the*
18 *tablets" and that's how it went until I got a good reading regularly, good readings".*
19

20
21 *(Patient 7)*
22

23
24 Some patients also changed the way they accessed services because they now knew what they
25 wanted e.g. bypassing the practice nurses and going directly to the GP because they thought the
26 nurse could not prescribe a change in medication.
27

28
29 When the data were presented for validation to a discussion group of patients, professionals and
30 researchers, it is this theme, of adapting to new roles and responsibilities, which dominated the
31 discussion. Echoing the themes presented above, patients in the discussion group emphasised the
32 role of telemetry-enabled home monitoring as being motivating, an incentive to improve self-care
33 and evidence which facilitated meaningful conversation and dialogue with professionals. However,
34 despite having been presented with the qualitative data on increased professional workloads and
35 contact with patients (the figures from the trial were not available at that point), they thought that
36 in the longer term home monitoring should lead to a reduction in the need for surgery attendance
37 which would be appreciated by patients. The need for clarity in roles (what the patient was
38 expected to do and what the practice was expected to do) was emphasised.
39
40
41
42
43
44
45
46
47
48

49 Discussion

50 Both patients and clinicians participating in this study considered that a measurement based on the
51 average of multiple readings from the home monitoring system was trustworthy and could be used
52 as a basis for action. Although patients generally saw hypertension as a lifestyle issue and were
53 aware of lifestyle interventions, only a few achieved significant lifestyle changes during the trial and
54 some were from the control group. However, the system was described by patients as a motivator
55
56
57
58
59
60

1 to achieve BP control and the instantly available, shared and trusted reading facilitated more rapid
2 tailoring of medication. This was partially driven by patients who increased their engagement with
3 the medical management of their condition, initiating contacts and negotiating treatment, and
4 partially by the healthcare professionals who contacted people with unsatisfactory readings. The
5 cost to the practices of achieving improved BP control was increased patient contacts and workloads
6 for professionals during the trial (where all participants had uncontrolled BP at the start). However,
7 when this outcome was discussed with patients and professionals they expressed the view that in
8 the longer term the system could reduce the need for surgery visits. There was an example of this
9 where one patient described asynchronous communication with the practice in the form of email
10 which resulted in tailoring of medication without the need for frequent phone calls and surgery
11 visits.
12
13
14
15
16
17
18
19

20 Prior to the intervention, patients differed in their levels of concern about their hypertension and
21 some already owned home monitors and there was a trend within the trial data for those who
22 already used home monitors to show greater improvement in their BP. This is consistent with the
23 health beliefs model of behaviour³⁰ where perceived severity of the condition is one of the factors
24 influencing health behaviour. Some clinicians were concerned that, for a small number of people,
25 monitoring and increased engagement in the medical management of their hypertension may have
26 provoked anxiety or dependency. This was echoed by one patient although generally increased
27 engagement seen to be a positive change by both patients and clinicians.
28
29
30
31
32
33
34

35 Within the practices, doctors and nurses found that traditional ways of working, which prioritise face
36 to face consultations and split responsibilities for BP monitoring and anti-hypertensive prescribing,
37 may not easily support the increased patient engagement or rapid treatment adjustment that
38 successful telemonitoring requires and there was some evolution of working practices during the
39 study. A lack of integration of telemonitoring data with the patients' electronic records also limited
40 multi-disciplinary working within the practices. The acceptance by professionals that they had an
41 accurate estimate of the patients' BP raised questions about the best management when BP was
42 near the recommended level which was not covered in the guidelines available at the time.
43
44
45
46
47
48
49

50 The strengths of the study are that it is based on real experience of using the systems and, because
51 the protocol permitted evolution in practice, it gives an indication of some of the issues which would
52 need to be addressed for BP telemonitoring to be used in routine practice. These include integrating
53 of telemonitoring data with the electronic patient record, enabling communication channels
54 between patients and professionals which are rapid and efficient for both, implementing inter-
55 professional working practices which support rapid tailoring of medication and additional clinical
56

1 guidance. The review by Mair et al³¹ on factors affecting the success of telehealth implementations
2 chimes with many of these, as do earlier qualitative studies such as May et al³². Feedback from
3 participants and triangulation with trial data add weight to these interpretations. However, practices
4 were only involved in the trial for a short period (about 8 months) and evolution of practice to meet
5 the needs of patients who are telemonitoring could be limited by factors which have not yet been
6 identified. It is also possible that both patients and practices who agree to participate in a trial may
7 differ in some way from those who choose not to participate, and thus not all opinions about
8 telemonitoring may have been captured. A request to seek opinions about telemonitoring from
9 those who did not want to participate in the trial was declined by the Ethics Committee. A weakness
10 of the study was that triangulation data showing the effectiveness of the intervention amongst those
11 who already owned a home monitor was only received after the end of data collection and the
12 opportunity was lost to interview more of this group and more systematically investigate what they
13 considered that telehealth added to their home monitoring.

22
23

24 No direct comparators to this qualitative study, which examined telemonitoring provided in a usual
25 care context, have been found. The HITS trial¹⁶, which was the context for this study, showed that
26 patients using telemonitoring in their usual primary care setting had a greater reduction in BP than
27 the control group. Patients found the equipment easy to use and the measurements easy to
28 understand. This was similar to experience reported in other studies with effective interventions
29 incorporating telemonitoring such as TASMINGH2,¹³ and differed from a recent US based study
30 where difficulties in using the system were reported³³ and the effect was much smaller.¹⁹ System
31 design (hardware, software and the associated guidance and support) clearly has a part to play, and
32 providing the service via the patient's usual practitioners, rather than as a separate stand-alone
33 service, may have also helped in terms of patient support. There is also a possibility that some of the
34 usability issues may be related to the populations involved. In the US study issues with poor literacy
35 were identified³³ whereas, although the population for the trial which underpinned this study¹⁶ was
36 drawn from across the spectrum of social privilege and deprivation in Scotland, this was not a
37 concern raised at any point. In some of the trials of larger interventions incorporating BP
38 telemonitoring^{12,18,19}, it is hard to unravel the impact of the telemonitoring from the impact of the
39 rest of the intervention. This study, and the trial outcome, suggests that the telemonitoring itself can
40 overcome some of the barriers to improved BP control. The added value of the additional
41 interventions such as pharmacist support¹² or medication self-management plans¹⁸ needs to be
42 determined. Interestingly, the qualitative study associated with a trial which included telemonitoring
43 and medication self-management suggested that although many participants would be happy to
44 continue with the telemonitoring, few would be happy to continue with the medication self-
45 management plans.¹³

3 The consensus amongst the professionals interviewed was that a nurse-led monitoring service would
4 be most appropriate, but some patients perceived that nurses could not prescribe the changes to
5 medication which the patients thought they needed. This could be a limiting factor on the efficiency
6 of the service. The legislative and training framework for independent nurse prescribing has been
7 established in Scotland ³⁴ but the number of nurse prescribers is still very limited, although
8 growing.³⁵ Increasing nurse prescribing in long-term conditions may be key to providing the
9 organisational infrastructure to maximize the efficiency of this model of telemonitoring. Integration
10 of the telemonitoring data with electronic patient records would also be essential; patients are free
11 to consult with other members of the primary health care team and expect their BP data to be
12 available. Further consideration needs to be given to the workload issues for the practices involved.
13 The trial did increase their workloads¹⁶, but the discussion group considered that telemonitoring
14 could reduce the need for practice visits in the longer term. This raises the question of whether
15 telemonitoring should be a short or longer term intervention. A model where initial professional
16 surveillance of BP gives way to patient self monitoring once control is established, should be
17 investigated.

26
27
28
29
30 In conclusion, this qualitative study indicates that in a UK context BP telemonitoring in a usual care
31 setting can provide a trusted basis for medication management and improved BP control. It
32 increases patients' engagement in the management of their condition, but professional time for
33 supporting telemetry support and greater patient engagement can increase workloads and demand
34 changes in service organisation. However, if these issues are overcome, BP telemonitoring could be
35 an effective tool in the management of hypertension.

Contributions and Declaration

Contributors: Brian McKinstry, Janet Hanley and Claudia Pagliari designed the study. Janet Hanley and Brian McKinstry led the research. Jenny Ure collected the data and led the analysis. Aziz Sheikh provided advice throughout the trial. All authors were involved in writing the paper.

Funding: This study was funded by the BUPA Foundation with additional support from the High Blood pressure Foundation and NHS Lothian. Brian McKinstry and Janet Hanley were during the course of the study supported by the Scottish Chief Scientist Office. The funders had no role in the analysis, writing up of the results or decision to publish. The researchers were independent of the funders.

Competing interests: All authors have completed the Unified Competing Interest form at www.icmje.org/coi_disclosure.pdf (available on request from the corresponding author) and declare: no support from any organisation for the submitted work; no financial relationships with any organisations that might have an interest in the submitted work in the previous 3 years; no other relationships or activities that could appear to have influenced the submitted work

All authors had full access to all of the data in the study and can take responsibility for the integrity of the data and the accuracy of the data analysis.

Box 1 Description of the telemonitoring intervention

The intervention

The practices and patients were asked to use a system which comprised a validated electronic home BP monitor and mobile phone technology that enabled the transfer of BP readings via SMS to a secure website which was accessible to the user and their doctor or nurse, and also provided automated feedback to the patient. The BP monitor linked to a mobile phone wirelessly, via Bluetooth. The components of the intervention were:

Home BP monitoring: Patients were asked to record their BP as agreed with the healthcare team, or more frequently as they wished. Guidance was initially to record BP twice in the morning and twice in the evening for a week in line with the European guideline on BP monitoring, to build a baseline average. Thereafter, they were asked to take weekly measurements preferably at different times of day if their average BP was within the recommended range, but if they had made any lifestyle or medication change which would impact on their BP, they were asked to measure their BP for a more intensive period of monitoring to allow the rolling average to change and to more quickly assess the effect.

Transmission of data: This simply required the phone to be switched on and to have a signal when the BP measurement was taken. Patients just had to apply the cuff and press a button on the BP monitor. The reading and transmission occurred automatically. Mobile phone problems did not lead to loss of data because all readings were stored in the monitor and any untransmitted readings were sent when the next reading was taken.

Feedback to patients (closed loop feedback): In addition to optionally accessing their BP record on-line, patients could also opt to receive reports via text message or email. These gave advice on the current status of their BP based on the average of the last 10 readings, and whether they should contact their doctor or nurse. Reports were generated every 10 readings or weekly, whichever was sooner, with a reminder to check BP if this had not been done. These reports could reassure them that their average BP was within target (<135/85mmHg) or tell them that their BP average was improved on the last report but not yet to target and to maintain current therapy, or that their BP was not at target and that they should contact their clinician. If an individual BP reading was very high (>220/120mmHg) an immediate text or email report was generated reinforcing the written advice in the patient information leaflet to rest for 30 minutes, check again and contact the practice if BP remained very high.

Sharing the readings with the healthcare team: Members of the healthcare team were able to access the records of their patients online via a secure login to a summary screen which listed their patients, their average BP over the last 10 readings, and the date of their last reading. Average BPs outside the recommended limits (set at 135/85mmHg for the study) were highlighted. Clicking on the each individual patient led to lists or graphs of all their readings. Clinicians could then check the patients' electronic GP record to see if there had been recent advice regarding medication or lifestyle change and if not, could contact the patient to make a change. Clinicians were recommended to check the website weekly, but the frequency of log-on could be chosen by them.

Usual Care

Patients allocated to the usual care group were asked to continue to attend the practice for BP checks according to the usual routine of the practice. If they were already home monitoring they were not discouraged from continuing.

All patients

For all patients the GP/practice nurse were informed that the ambulatory monitoring used to screen for eligibility for the HITS trial had shown that their average BP was above the target range, but they were not given the actual reading. All patients were given an information pack containing a range of publicly available leaflets on hypertension management and lifestyle modification.

What This Paper Adds

The trial which formed the context for this paper shows that BP telemonitoring integrated into hypertension patients' usual primary care provision can lead to improvements in management. However, it is a complex social intervention and the qualitative literature on BP telemonitoring, which is mainly based on trials where the telemonitoring is only part of a larger intervention, or there is little involvement of the usual care provider, does not explain why telemonitoring in this context is effective, or what may be required for the success of the trial to be translated into routine care.

This study showed that both patients and professionals were reluctant to increase medication based on single BP measurements taken in the surgery. The telemonitoring measurements based on multiple readings were perceived as being more accurate and there was a willingness to act on them. Patients using telemonitoring became more engaged in the management of their condition. Professionals found that telemonitoring increased their workloads, and some changes in working practices were needed to support it effectively.

APPENDIX 1: Topic Guides for interviews with the healthcare team and patients

Nurse/GP Topic Guide v2.

Experience of using the system

- how they use it/ find it?
- day to day management
- problems/concerns
- technical issues?
- clinical issues?
- organisational issues?

Impact on how BP managed by care team

- has it changed management of BP
- communication with care team
- changes to medication
- adherence to treatment regime
- impact of feedback
- workload
- re-organisation

Impact on how BP managed by patients

- how they use it
- changes in way they see /manage their condition
- anxiety / reassurance/ control/passive/active/self-care
- impact of feedback on
- medicalisation (e.g. some patients found the monitoring made them focus too much on being ill, and not enough on being well)

Implications for use in practice

Patient Topic Guide + Prompts v.2

Non-monitored and Monitored Groups

Experience of the screening process

- own monitor?
- impact?

How they manage their BP / feel about managing it

- day to day management
- do they comply or not with advice and if so why / why not
- anxiety
- adherence to regime/lifestyle and drug tmnt
- sense of control
- have they changed the way they see /manage their condition/if so why

Experience of managing BP with monitor/ without monitor

- technical
- clinical
- personal (anxiety; reassurance)
- organisational

What advice given

- what did they think of advice given
- other factors in lifestyle that might affect this
- what were they told by GP or nurse / what did they understand? do they see it differently?
- do they feel that suggestions are not appropriate for them? Why?

Have views of/ approaches to management changed since first diagnosis / if so why

- information/advice
- readings
- opportunities to change
- other factors – e.g. life events, illness, GP advice

How they feel about it / want to deal with it

1 impact on lifestyle
2 sense of control / anxiety/ reassurance
3 inconvenience

4 **Additional Themes for Monitored group**

5 Describe how they use it in practice
6 Experience of how nurse/doctor has used it
7 Perceived impact?
8 onQoL?
9 on seeking help?
10 on care
11 onself care/self management?
12 facilitate passive or active control
13 on understanding of BP
14 on communication with care team
15 on appointments.

16 Perceived benefits
17 Perceived problems
18 Which groups would benefit from it in particular?

R Relevance of study question

To explore the experiences of patients and professionals taking part in a randomised controlled trial (RCT) of remote blood pressure (BP) telemonitoring supported by primary care. To identify factors facilitating or hindering the success of the intervention and those likely to influence its potential translation to routine practice.

A Appropriateness of qualitative method

Qualitative study adopting a qualitative descriptive approach

T Transparency of procedures

Sampling

Is the sampling strategy appropriate?

Twenty five patients, 11 nurses and 9 doctors who were participating in an RCT of BP telemonitoring. A maximum variation sample of patients based on age, sex, and deprivation status of the practice was sought.

Recruitment

Was recruitment conducted using appropriate methods?

Patients participating in the trial were purposively sampled and checks were made with the practice to ensure that it was still appropriate to approach the patient before they were contacted by letter. Those who did not respond were replaced by patients with similar characteristics.

Is the sampling strategy appropriate?

Could there be selection bias?

Thirty four patients were approached (28 from the intervention arm and eight from the control arm) and 25 patients (5 from the control arm of the trial) participated.

The patient characteristics are shown in Table 1. Eleven practice nurses (all female) and 9 GPs (4 male, 5 female) took part. Non-participation in the interviews was mainly due to difficulty in arranging a suitable time

Data collection

Was collection of data systematic and comprehensive?

Interview guide provided

Are characteristics of the study group and setting clear?

Table 1 gives description of each patient

Why and when was data collection stopped, and is this reasonable?

Data saturation

Role of researchers

Is the researcher(s) appropriate? How might they bias (good and bad) the conduct of the study and results?

Interviews were carried out by JU, an experienced female qualitative researcher with a background in education and psychology who was not involved in the RCT

Ethics

Was informed consent sought and granted?

Patients were made aware that they may be approached for the embedded qualitative study when they agreed to participate in the trial, but that participation in this study would be optional. Patients and professionals approached were sent a separate information sheet about the qualitative study and signed an additional consent prior to participation

Were participants' anonymity and confidentiality ensured?

Patients identified by number

Was approval from an appropriate ethics committee received?

The study received ethical approval from the South East Scotland Ethics Service (08/S1101/38) and R&D approval from NHS Lothian.

S Soundness of interpretive approach

Analysis

Is the type of analysis appropriate for the type of study?

- *thematic*: exploratory, descriptive, hypothesis generating
- *framework*: e.g., policy
- *constant comparison/grounded theory*: theory generating, analytical
-

Are the interpretations clearly presented and adequately supported by the evidence?

Are quotes used and are these appropriate and effective?

Was trustworthiness/reliability of the data and interpretations checked?

All interviews were recorded, fully transcribed and the transcript checked against the recording. They were analysed thematically with initial codes and themes identified inductively from the data.

Appendix 2 shows the codes, (with the number of text extracts coded against each), and how they have been grouped into themes and overarching themes.

Constant comparison was used to ensure consistency in coding and negative cases were sought for each coding category. Coding was checked and iteratively refined using paired analysis of transcripts by two researchers. Researcher reflexivity was supported by discussing emerging findings with the wider research group where different explanations were explored and the coding and thematic analysis

reviewed and refined. Following this, the thematic analysis was presented by JH to a discussion group of 21 patients, professionals and researchers who had participated. The presentation introduced the themes and illustrative quotes and the whole dataset (all the text associated with each code) was made available to the participants. Where it was possible to triangulate findings arising from the qualitative data against the quantitative trial data (eg workload impacts), this was also done

Discussion and presentation

Are findings sufficiently grounded in a theoretical or conceptual framework?	The themes were grouped into the four overarching themes presented here. The groupings were broadly informed by the purpose of the study and also by the normalisation process
Is adequate account taken of previous knowledge and how the findings add?	model as applied to telehealth, with its constructs of interactional workability, relational integration, skill set workability and contextual integration. Additional theoretical perspectives are considered in the discussion
Are the limitations thoughtfully considered?	Strengths and limitations explicitly described and discussed
Is the manuscript well written and accessible?	

Are red flags present? These are common features of ill-conceived or poorly executed qualitative studies, are a cause for concern, and must be viewed critically. They might be fatal flaws, or they may result from lack of detail or clarity.

Abstract

Objectives: To explore the experiences of patients and professionals taking part in a randomised controlled trial (RCT) of remote blood pressure (BP) telemonitoring supported by primary care. To identify factors facilitating or hindering the effectiveness of the intervention and those likely to influence its potential translation to routine practice.

Design: Qualitative study adopting a qualitative descriptive approach.

Participants: Twenty five patients, 11 nurses and 9 doctors who were participating in an RCT of BP telemonitoring. A maximum variation sample of patients from within the trial based on age, sex, and deprivation status of the practice was sought.

Setting: Six primary care practices in Scotland.

Method: Data were collected via taped semi-structured interviews. Initial thematic analysis was inductive. Multiple strategies were employed to ensure that the analysis was credible and trustworthy.

Results: Prior to the trial both patients and professionals were reluctant to increase medication based on single BP measurements taken in the surgery. BP measurements based on multiple electronic readings were perceived as more accurate as a basis for action. Patients using telemonitoring became more engaged in the clinical management of their condition. Professionals reported that telemonitoring challenged existing roles and work practices and increased workload. Lack of integration of telemonitoring data with the electronic health record (EHR) was perceived as a drawback.

Conclusions: BP telemonitoring in a usual care setting can provide a trusted basis for medication management and improved BP control. It increases patients' engagement in the management of their condition, but supporting telemetry and greater patient engagement can increase professional workloads and demand changes in service organisation. Successful service design in practice would have to take account of how additional roles and responsibilities could be re-aligned with existing work and data management practices

The embedded qualitative study was included in the protocol for the HITS trial registered with ISRCTN no. 72614272.

Summary

Article Focus

- Qualitative exploration of the experiences of patients and professionals taking part in a randomised controlled trial (RCT) of remote blood pressure (BP) telemonitoring supported by primary care.
- Identification of factors facilitating or hindering the success of the intervention and those likely to influence its potential translation to routine practice

Key Messages

- BP telemonitoring in a usual care setting can provide a trusted basis for medication management and improved BP control.
- It increases patients' engagement in the management of their condition,
- Supporting telemonitoring and greater patient engagement can increase professional workloads and demand changes in service organisation.

Strengths and limitations of this study

The strengths of the study are that it is based on experience of using the systems by the patients' own practitioners in a usual care context. The trial context permitted triangulation with quantitative data. Because the protocol permitted evolution in practice, it gives an indication of some of the issues which would need to be addressed for BP telemonitoring to be used in routine practice. The weaknesses are that participation in the study was relatively short for each practice with limited patient numbers so any longer term barriers to evolution in practice were not identified. It is also possible that participants in this study differ from non-participants.

Background

Long term illness is increasingly prevalent and telemonitoring (remote self-monitoring of health parameters with electronic transmission of data to a health care provider) is considered to be a promising way of supporting patient care within existing resources.¹ However, despite policy statements and numerous pilots, telemonitoring has not yet been widely adopted.² This qualitative study examined patient and professional experiences of BP telemonitoring in the context of an RCT. As an embedded qualitative study its purpose was to help explain the trial results and to generate insights regarding factors likely to influence the adoption of this approach within routine care.

Hypertension (persistently raised BP >140/90 mmHg), is a major cardiovascular risk factor, which is frequently poorly controlled,³ with evidence of under treatment in many cases, sometimes described as 'therapeutic inertia'.⁴ This is despite the availability of guidelines^{5,6} or (as in the UK) financial incentives to primary care doctors.⁷ In day-to-day practice effective assessment of BP is problematic. Single BP measurements taken in the surgery are poorer indicators of risk than estimates based on multiple measures from ambulatory or home monitoring^{8,9,10} and 'white coat hypertension' – raised BP when measured in the surgery, but not at home¹¹ – is a complicating factor. However, for practical reasons, surgery-based measurements are still the basis of treatment decision making in most cases. Telemonitoring can overcome these measurement issues by allowing patients to take multiple BP readings at home and share them with healthcare professionals in almost real time, potentially providing motivation for improvements in self-care whilst facilitating professional input if necessary. Although we have been unable to identify previous qualitative studies of telemonitoring in hypertension in a usual care setting, some common themes are emerging from qualitative studies where the self-monitoring was either part of a larger intervention such as specialist nursing support or self-management of medication,^{12,13} or the patients were simply self-monitoring with no data transmission.^{14,15} The common themes were that patients generally find self-monitoring to be a positive experience which is empowering, reassuring and motivational.

The trial which formed the context for this study¹⁶ (see Box 1 for summary of the intervention) involved patients from primary care hypertension registers whose surgery BP measures in the previous 6 months had been > 140/90mmHg, who had a BP higher than 135/85mmHg on daytime ambulatory BP monitoring performed as screening for the trial, and did not have diabetes, previous stroke or transient ischaemic attack, atrial fibrillation or other major illness. It found that for those using telemonitoring, BP reduced by a mean of 4.3/ 2.6 mmHg compared with the group receiving usual care. Other trials in this field also strongly suggest that telemonitoring in hypertension can be effective in achieving clinically important reductions in systolic and diastolic BP^{17,18} but some studies

1 have shown poorer outcomes.¹⁹ The introduction of telemonitoring may be regarded as a complex
2 sociotechnical intervention involving changes in behaviour in addition to a purely technological
3 solution. It is therefore important to understand how components of the intervention and
4 contextual factors contribute to the outcome.²⁰ These issues can be difficult to explore using
5 quantitative methods alone²¹ and proponents of 'realist evaluation' suggest using qualitative
6 methods to tease out what works in different contexts.²² The aim of this study, therefore, was to
7 qualitatively explore the experiences of patients and professionals taking part in a trial of BP
8 telemonitoring based in a usual care setting, to identify what contributed to the effectiveness of the
9 intervention, what limited its effectiveness and what may be required for the success of the trial to
10 be translated into routine care.

22 **Methods**

23 **Overview**

24 This study was embedded within an RCT of BP telemonitoring in routine care for patients whose BP
25 was above target¹⁶ (Box 1). A qualitative descriptive approach was employed,²³ acknowledging that
26 in health services research the need of the researcher is not simply to provide a description of the
27 phenomenon, but also to produce an interpretive account which will help to guide health care
28 innovation whilst, at the same time, recognising the subjective nature of the encounter between
29 the subject and the researcher.²⁴

37 **Ethics and governance considerations**

38 The study received ethical approval from the South East Scotland Ethics Service (08/S1101/38) and
39 R&D approval from NHS Lothian. Patients were made aware that they may be approached for the
40 embedded qualitative study when they agreed to participate in the trial, but that participation in this
41 study would be optional. Patients and professionals approached were sent a separate information
42 sheet about the qualitative study and signed an additional consent prior to participation.
43
44
45
46
47

48 **Sampling and recruitment**

49 Twenty GP practices and 401 patients participated in the RCT. Of these, patients and staff from five
50 socio-economically diverse practices (based on the Scottish Index of Multiple Deprivation²⁵) were
51 initially approached to participate in the qualitative study. A sixth practice was added later to
52 increase the number of professionals participating and ensure data saturation. A maximum
53 variation patient sample of at least 20 patients overall from these practices was sought based on
54

1 age, sex, and the deprivation status of the practice. Patients participating in the trial were
2 purposively sampled and checks were made with the practice to ensure that it was still appropriate
3 to approach the patient before they were contacted by letter. Those who did not respond were
4 replaced by patients with similar characteristics. The aim of this sampling strategy was to capture a
5 broad range of patient experiences across the socio-economic spectrum included within the trial.
6
7
8
9

10 11 12 **Data generation and handling**

13 Qualitative data were gathered through semi-structured interviews with patients, nurses and
14 doctors. The initial topic guides were based on issues identified by our previous acceptability
15 study²⁶ and interviews with patients participating in the trial pilot study. The interview topic guides
16 were refined iteratively in response to the initial interviews. The final topic guides are shown in
17 Appendix 1. Most patients were interviewed face-to-face in their own home, and professionals at
18 their workplace, with interviews carried out by telephone where this was not possible. Most
19 healthcare professionals were interviewed individually, but two nurses were interviewed together,
20 as were three doctors. Interviews were carried out by JU, an experienced female qualitative
21 researcher with a background in education and psychology who was not involved in the RCT.

33 **Data handling and analysis**

34 The data were collected between July 2009 and June 2010 and, with a little variation due to
35 availability, in tranches reflecting different start dates of different practices. Provisional coding and
36 identification of themes took place after each tranche of interviews. Interviewing continued until
37 the researcher, in discussion with the wider research team, considered that data saturation was
38 achieved. Although there is discussion on the concept of data saturation, in the context of this study
39 which was focused and involved a relatively homogeneous population, data saturation was
40 considered to have occurred when the researcher was not identifying any new themes or codes
41 within the provisional themes in sequential interviews, and thought this would be unlikely in
42 subsequent interviews. Detailed re-coding and checking took place from May-December 2010 with
43 the validation focus group taking place in May 2011.

8 each coding category. Coding was checked and iteratively refined using paired analysis of transcripts
9 by two researchers. Researcher reflexivity was supported by discussing emerging findings with the
10 wider research group where different explanations were explored and the coding and thematic
11 analysis reviewed and refined. Following this, the thematic analysis was presented by JH to a
12 discussion group of 21 patients, professionals and researchers who had participated. The
13 presentation introduced the themes and illustrative quotes and the whole dataset (all the text
14 associated with each code) was made available to the participants. This discussion, which lasted for
15 90 minutes, was moderated by BM, recorded, transcribed and coded. It was used to validate the
16 initial grouping of data into codes and themes, but also to extend the discussion of how telehealth
17 may change the provision of primary care. The coding is shown in Appendix 2.
18
19

20
21 The themes were grouped into the four overarching themes presented here. The groupings were
22 broadly informed by the purpose of the study and also by the normalisation process model as
23 applied to telehealth, with its constructs of interactional workability, relational integration, skill set
24 workability and contextual integration²⁷. Appendix 2 shows the codes, (with the number of text
25 extracts coded against each), and how they have been grouped into themes and overarching
26 themes. Where it was possible to triangulate findings arising from the qualitative data against the
27 quantitative trial data (including workload impacts, lifestyle change and the impact of telemonitoring
28 compared with simple home monitoring), this was also done. Three overarching themes are
29 presented here. The fourth theme comprised comments about the study and is shown in Appendix
30 2.

43 Results

44
45 Thirty four patients were approached (28 from the intervention arm and eight from the control arm)
46 and 25 patients (5 from the control arm of the trial) participated. The patient characteristics are
47 shown in Table 1. Eleven practice nurses (all female) and 9 GPs (4 male, 5 female) took part. Five
48 patients from the control group were interviewed because it was possible that their treatment may
49 have been different than usual during the trial. There was no evidence from the interviews that this
50 had happened. The telemonitoring service employed in this study was novel in that self-monitoring
51 was integrated with usual care. For this reason we present the patient and professional data
52
53
54
55
56
57
58
59
60

1 together here, highlighting areas of concordance, divergence and evolution in practice both between
2 and within the professional and patient groups.

7 **The Patient Experience**

8
9
10 Patients' accounts of their response to the initial diagnosis of hypertension differed, as did their level
11 of concern and their personal approaches to self-management. Some were not concerned, did not
12 think of their hypertension often and left the management to their doctor or nurse. For others the
13 diagnosis had caused practical problems (e.g. in taking out life insurance) or anxiety, particularly
14 where they had experience of a family member suffering a stroke. Anxiety about what was
15 happening to their BP between appointments had led some to self-monitor their BP prior to this
16 study, and one practice provided patients with a home monitor to use during diagnosis. Contrasting
17 perspectives are illustrated in the quotations below.
18
19
20
21
22

23
24 *Oh I just take my tablet. I don't think about it....I'm not the worrying kindI don't*
25 *see the point in worrying over things.*

26
27 *(Patient 1, control group, previous experience of home monitoring with practice*
28 *monitor)*

29
30
31 *And I'm conscious of it because what I'm looking to do you do have to have a medical, and*
32 *blood pressure is one of the key things that they don't want, if you have high blood pressure*
33 *you're out. So I'm looking to get it down*

34
35
36 *(Patient 20, monitoring group, no previous experience of home monitoring)*

37
38
39 *I can't remember if they...if I was advised to go and buy a home monitoring machine but I*
40 *decided to do it anyway.....I knew that my blood pressure would be checked every time,*
41 *regularly at the surgery but certainly twice a year, but until that I would like more*
42 *information than that.*

43
44
45 *(Patient 4, control group, previous experience of home monitoring with own monitor)*

46
47 The differing levels of patient concern about hypertension at the start of the study is clearly a factor
48 which could influence outcomes, but was not something which was directly measured in the trial¹⁶.

49
50
51 Patients saw hypertension largely as a lifestyle issue and many tried to ascribe a cause within their
52 lifestyle such as reduced physical activity and stress, although some also mentioned familial
53 tendency to high BP.
54
55
56
57
58
59
60

1 *"I wasn't say like grossly overweight, I wasn't...didn't smoke at all, it was difficult to...I mean I*
2 *did have a more difficult lifestyle at the time, a lot of commuting, a lot of driving"*

3
4
5 *(Patient 6, monitoring group, no previous experience of home monitoring)*

6
7 Most were aware that lifestyle change could help control BP and had been given advice. Lifestyle
8 advice was received from multiple sources and perceived to be general rather than being targeted at
9 the reasons for them individually developing hypertension.
10

11
12
13 *"...a proper balanced diet and not too much fat and all these sort of things. But it's strange if*
14 *anyone doesn't know about that nowadays"*

15
16 *(Patient 17, monitoring group, no previous experience of home monitoring,)*

17
18
19 Some participants had modified their lifestyle prior to the trial in response to the diagnosis of
20 hypertension
21

22 *What I did do [when diagnosed with hypertension] and I've stuck to it, I've cut out salt. I was*
23 *overweight a few years ago and I cut out butter, so now I don't have butter and I don't have*
24 *salt. (I) just (use) general knowledge, just tried to reduce salt, reduce weight. And salt brings*
25 *up your blood pressure so...*

26
27
28 *(Patient 12 monitoring group, no previous experience of home monitoring)*

29
30
31
32
33 Some of the patients interviewed had modified their lifestyle during the trial, and considered that
34 the system provided motivation
35

36 *"... I had lost a stone in weight during the course of that six months as well that I was being*
37 *on the monitor and I think that did. I think that was a contributory factor to my BP balancing*
38 *out"*

39
40
41 *(Patient 7, monitoring group, previous experience of home monitoring with practice*
42 *monitor)*

43
44
45 *"When I was taking the blood pressure I couldn't bear looking at a hundred and forty, a*
46 *hundred and fifty over a hundred and ten and I wanted to just be able to see better readings*
47 *in a way. So over the summer as well, starting to get more walking exercise, that kind of*
48 *thing.... I didn't want beta blockers because they had various side effects which..... I kind of*
49 *felt the conventional medicine options were maybe a bit limited in terms of what I wanted*
50 *out of it or in terms of avoiding side effects, so it did spur me on to look for alternative..."*

51
52
53
54
55 *(Patient 2, monitoring group, no previous experience of home monitoring,)*

1 *"So I like having the machine there because it prompts me, and I've done things like I've done*
2 *some exercise and then I've taken my blood pressure to see whether it has made an impact,*
3 *and it did, it does, every time."*

4
5
6 *(Patient 20 monitoring group, no previous experience of home monitoring,)*
7
8
9

10
11 However, many others were aware of the need for lifestyle change but found it too difficult to
12 implement .
13

14
15 *"...obviously I'm overweight, I'm trying to do something about that but it just doesn't*
16 *happen".* *(Patient 4,*
17
18 *control group, previous experience of home monitoring with own monitor)*
19

20
21
22
23 The quantitative results of the trial¹⁶ did not show any significant changes to lifestyle variables
24 relating to diet, exercise or medication adherence in either the intervention or control groups.
25 However, closer examination of the trial data did show that in both groups a small number of
26 individuals (10 overall) had, as described by Patient 7, lost more than 1 stone (6.5Kg) in weight.
27
28
29

30
31
32 Using the system increased some patients' engagement with the medical management of their
33 hypertension. They used it to negotiate treatment and, in a very small number of cases, titrate their
34 own medication.
35
36
37

38
39
40 *"It's certainly given me more meaningful data to speak to the doctor rather than, "Well, I*
41 *think my BP has probably gone up." "*

42
43
44 *(Patient 6, monitoring group, no previous experience of home monitoring)*
45
46
47

48
49 *"...I've got 16 milligrams and eight milligrams [tablets of antihypertensive drug] and the last*
50 *time I saw Dr B he said; the maximum you can have is 32. Well what I probably could do is go*
51 *and see the nurse and say can I take it upon myself to move it up to 32 by taking another*
52 *eight"*
53
54
55

56
57 *(Patient 19, monitoring group, no previous experience of home monitoring)*
58
59
60

1 These data suggest that the interaction between patient and doctor or nurse facilitated by the
2 telemetry is important rather than just the home monitoring. This is supported by trial data where it
3 was possible to compare outcomes between the telemonitoring group and control group for the
4 30% of patients who had self-monitored prior to the trial (this analysis was not included in the
5 published trial results). Within this group, those randomised to telemonitoring had a mean
6 reduction in systolic daytime ambulatory BP of 7.16mmHg (95% CI 3.67 to 10.64mmHg) compared to
7 those receiving usual care.
8

9 Generally, both patients and professionals thought the increased patient engagement in BP
10 management was beneficial.
11

12
13
14
15
16
17 *"Yes. I really thought that it (system) was a brilliant idea. And it has helped me a lot, to*
18 *understand more"*
19

20
21 *(Patient 6, monitoring group, no previous experience of home monitoring)*
22

23
24
25
26 *"...the positive thing about it was it definitely helps patients to become much more involved*
27 *in their care which is a good thing and they definitely take much more interest in it I think*
28 *because they're measuring it, they can see it, you know it's much more real to them I think"*
29

30
31
32 *(Practice Nurse 9)*
33

34 However, a note of caution was sounded, again by both patients and professionals, that for a small
35 number of people home monitoring could provoke anxiety
36

37
38 *"I felt it was intrusive. I started worrying about my BP"*
39

40
41 *(Patient 12 monitoring group, no previous experience of home monitoring,)*
42

43
44
45
46 *"....and then you've got others; 'Oh, I feel a bit ill today, I'll better check my BP'... and I think*
47 *that that's the danger of home monitoring, I think people can become obsessed with it..."*
48

49 *(Practice Nurse 6)*
50

51 Although both patients and professionals raised the issue of anxiety generated by home monitoring,
52 it was a much stronger theme amongst the professionals. It was only raised by one patient during
53 the interviews, but several professionals. This accords with our previous telehealth work where
54 there is considerable concern amongst professional about the possibility of telehealth putting
55
56
57
58
59
60

1 patients in a 'sick role' and making them dependent or anxious, but this concern is not widely
2 echoed by patients^{28, 29}.
3
4
5
6

7 **Using the telemonitoring system**

8
9
10 The simple telemonitoring system used in this study generally worked well, although some design
11 issues were highlighted as described below. Generally, patients had little difficulty measuring their
12 BP, transmitting their readings or finding a routine for measuring their BP. Some also accessed the
13 on-line record of their readings. However, the wording of the automated feedback messages sent by
14 the system to was not found to be valuable although the messages in themselves did remind some
15 patients to maintain their engagement with the system.
16
17
18
19

20
21 *"it's the same message from presumably a machine [laughs] which doesn't help a lot.*
22 *Because it's obviously coming from a machine and it tells me have I contacted my medical*
23 *practice or nurse, which I have but it doesn't seem to know that, you see? "*
24

25
26 (Patient 9, monitoring group, previous experience of home monitoring with practice
27 monitor)
28
29

30 The main clinical advantage provided by the system was that that it facilitated management of BP
31 using average BP, based on multiple readings taken at home, which was seen by both patients and
32 professionals as a more trustworthy basis for action than single BP measurements taken in the
33 surgery. Both patients and professionals commented that, prior to the system being introduced,
34 there were sometimes long delays in initiating appropriate treatment in people with less markedly
35 raised BP, driven by reluctance by healthcare staff to prescribe medication which may not be
36 absolutely necessary. The data from the patients who were not in the intervention group suggested
37 that, for them, medication changes remained infrequent and this was supported by the trial data¹⁶.
38
39
40
41
42
43

44 *"[prior to the trial]... you have a BP maybe 148 over 88, you might say 'let's see you again in*
45 *six months', when actually it's too high"* (Practice Nurse 10)
46
47

48 *"[prior to the trial] ...We're all guilty of it... 'we'll just see how it goes, you know, maybe watch*
49 *it. I'll check it again tomorrow' and they probably maybe sit on it a bit longer than they...it's*
50 *just a natural thing isn't it"* (Practice Nurse 9)
51
52

53
54 *"...and this patient in particular has been quite reluctant to increase the medication because*
55 *of her belief that her high BP is just a temporary thing because of what's going on her*
56 *life...she doesn't think that she should be on medication at all"* (Practice Nurse 11)
57
58
59
60

1 There was consensus between both patients and professionals that the home monitoring system
2 provided a more accurate assessment of BP than surgery measurements and better evidence for
3 action, facilitating rapid tailoring of medication.
4
5

6
7 *“you're getting a more accurate insight into true BP readings” (Practice Nurse 6)*
8

9
10 *“Well I tried everything. I had it on the table, I had my arm on a pillow and I was trying to*
11 *relax as much as I could, but there's no way you're going to cheat the machine so it's... it is a*
12 *good thing like. You cannot kid yourself on with it”*
13

14
15 *(Patient 6, monitoring group, no previous experience of home monitoring)*
16
17

18
19
20 One consequence of the professionals now feeling that they had an ongoing accurate estimate of
21 the patient's average BP was to raise new questions about what to do if it BP was near, but not at,
22 the target.
23

24
25 *“The only problem I had with it in a way is these people that were coming up as uncontrolled*
26 *who were one millimetre above the control level. And I just thought, oh come on, are you*
27 *really going to add in another drug to bring this down from 81 to 80?”*
28
29

30
31 *(GP1)*
32

33 For healthcare staff the main practical issue with the system was the lack of integration of the BP
34 data with the main patient electronic records and the fact that not all members of the healthcare
35 team regularly accessed the online system and were able to see the patient-recorded readings. This
36 caused problems when patients consulted with other members of the team.
37
38

39
40 *“...So they're coming in to see the doctor, the doctor takes their BP, one forty five ninety; ‘oh,*
41 *that's fine, what are you worried about?’ ... And then you go and you look at it the next*
42 *week and you think; they've seen the doctor and yet their BP's still really high”*
43
44

45
46 *(Practice Nurse 11)*
47

48 The trial thus flagged wider implementation issues such as the need for reconfiguration of work
49 practices to accommodate new roles, and ensure synergies across a more distributed care team, as
50 well as more integrated access to patient data from disparate data sources.
51
52

53 54 55 56 **Adjusting to new responsibilities and new ways of working** 57 58 59 60

1 The new service and increased patient engagement challenged organisation within practices.
2
3 Professionals reported that monitoring the electronic data, increased patient contact and the need
4 for more rapid decision making raised workloads. The consensus was that a nurse-led service would
5 be the best model, but monitoring the system needed to be an acknowledged part of the practice
6 nurses' role with regular formal time set aside for an electronic clinic. Not all practices succeeded in
7 monitoring the electronic data regularly throughout the trial. The trial data confirmed the increased
8 workload with patients in the telemonitoring group having, on average, two additional consultations
9 with the practice (one with the GP and one with the practice nurse, half of which were by telephone)
10 over the 6 months of the trial compared to the control group.¹⁶

11
12
13
14
15
16 Care had traditionally been face- to- face, but continuing to use this model to try to respond quickly
17 to the telemetry data had its frustrations.

18
19
20
21 *"We would phone them and say your BP's up, we need to increase your medication or you*
22 *need to come in and see someone ... And they never made appointments and then we had to*
23 *phone them again and say 'You've still not made an appointment, are you coming in?'"*

24
25
26 (Practice Nurse 3)

27
28 Some professionals began to change how they worked, reducing reliance on face-to-face contact
29 with the patients. Telephone contact increased although it was also found to be a time consuming
30 way of reaching patients who were frequently not available during working hours.

31
32
33 *"I feel like I'm phoning these patients all the time. If they can't get them in and you're having*
34 *to leave a message then you're going to have to leave a message in the book to make sure*
35 *they've got the message. You're checking to see if they've picked up a prescription because*
36 *you're then checking their blood pressure - it's still high - 'Have they taken their medication?'*
37 *You're phoning them... "*

38
39
40
41
42 (Practice nurse 4)

43
44
45
46
47
48
49 There was some experimentation in using email with appropriate safeguards and, although only a
50 small number were involved, this worked well.

51
52
53
54 *"...I got an email from the doctor every week from the readings and he was able to advise me*
55 *without me having to visit the doctor.*

56
57
58 (Researcher.... how did you feel about that?)

1 *Well I was quite happy with that. I thought that was great. It was very time saving for me.*

2
3
4 *(Researcher: Ahah. So you find the time saving aspect then very useful?)*

5
6 *Oh, yes, yes definitely. No effort making appointments, you just got an automatic email*
7 *every week. They give suggestions and like "Take more of the tablet's. "Take less of the*
8 *tablets"" and that's how it went until I got a good reading regularly, good readings".*

9
10
11
12
13 *(Patient 7, monitoring group, previous experience of home monitoring with practice monitor)*

14
15
16 Some patients also changed the way they accessed services because they now knew what they
17 wanted e.g. bypassing the practice nurses and going directly to the GP because they thought the
18 nurse could not prescribe a change in medication.

19
20
21 When the data were presented for validation to a discussion group of patients, professionals and
22 researchers, it is this theme, of adapting to new roles and responsibilities, which dominated the
23 discussion. Echoing the themes presented above, patients in the discussion group emphasised the
24 role of telemetry-enabled home monitoring as being motivating, an incentive to improve self-care
25 and evidence which facilitated meaningful conversation and dialogue with professionals. However,
26 despite having been presented with the qualitative data on increased professional workloads and
27 contact with patients (the figures from the trial were not available at that point), they thought that
28 in the longer term home monitoring should lead to a reduction in the need for surgery attendance
29 which would be appreciated by patients. The need for clarity in roles (what the patient was
30 expected to do and what the practice was expected to do) was emphasised.

31 32 33 34 35 36 37 38 39 40 41 **Discussion**

42
43 Both patients and clinicians participating in this study considered that a measurement based on the
44 average of multiple readings from the home monitoring system was trustworthy and could be used
45 as a basis for action. Although patients generally saw hypertension as a lifestyle issue and were
46 aware of lifestyle interventions, only a few achieved significant lifestyle changes during the trial and
47 some were from the control group. However, the system was described by patients as a motivator
48 to achieve BP control and the instantly available, shared and trusted reading facilitated more rapid
49 tailoring of medication. This was partially driven by patients who increased their engagement with
50 the medical management of their condition, initiating contacts and negotiating treatment, and
51 partially by the healthcare professionals who contacted people with unsatisfactory readings. The
52 cost to the practices of achieving improved BP control was increased patient contacts and workloads

1 for professionals during the trial (where all participants had uncontrolled BP at the start). However,
2 when this outcome was discussed with patients and professionals they expressed the view that in
3 the longer term the system could reduce the need for surgery visits. There was an example of this
4 where one patient described asynchronous communication with the practice in the form of email
5 which resulted in tailoring of medication without the need for frequent phone calls and surgery
6 visits.
7
8
9
10

11
12 Prior to the intervention, patients differed in their levels of concern about their hypertension and
13 there was an acknowledgement not all patients would respond to telemonitoring in the same
14 way. Some clinicians were concerned that, for a small number of people, monitoring and increased
15 engagement in the medical management of their hypertension may have provoked anxiety or
16 dependency. This was echoed by one patient although generally increased engagement seen to be a
17 positive change by both patients and clinicians.
18
19
20
21
22

23
24 Within the practices, doctors and nurses found that traditional ways of working, which prioritises
25 face to face consultations and where there may be split responsibilities for BP monitoring and anti-
26 hypertensive prescribing, may not easily support the increased patient engagement or rapid
27 treatment adjustment that successful telemonitoring requires and there was some evolution of
28 working practices during the study. A lack of integration of telemonitoring data with the patients'
29 electronic records also limited multi-disciplinary working within the practices. The acceptance by
30 professionals that they had an accurate estimate of the patients' BP raised questions about the best
31 management when BP was near the recommended level which was not covered in the guidelines
32 available at the time.
33
34
35
36
37
38
39

40 The strengths of the study are that it is based on real experience of using the systems and, because
41 the protocol permitted evolution in practice, it gives an indication of some of the issues which would
42 need to be addressed for BP telemonitoring to be used in routine practice. These include integrating
43 of telemonitoring data with the electronic patient record, enabling communication channels
44 between patients and professionals which are rapid and efficient for both, implementing inter-
45 professional working practices which support rapid tailoring of medication and additional clinical
46 guidance. The review by Mair et al³⁰ on factors affecting the success of telehealth implementations
47 chimes with many of these, as do earlier qualitative studies such as May et al³¹. Feedback from
48 participants and triangulation with trial data add weight to these interpretations. However, practices
49 were only involved in the trial for a short period (about 8 months) and evolution of practice to meet
50 the needs of patients who are telemonitoring could be limited by factors which have not yet been
51 identified. It is also possible that both patients and practices who agree to participate in a trial may
52
53
54
55
56
57
58
59
60

1 differ in some way from those who choose not to participate, and thus not all opinions about
2 telemonitoring may have been captured. A request to seek opinions about telemonitoring from
3 those who did not want to participate in the trial was declined by the Ethics Committee. A weakness
4 of the study was that triangulation data showing the effectiveness of the intervention amongst those
5 who already owned a home monitor was only received after the end of data collection and the
6 opportunity was lost to interview more of this group and more systematically investigate what they
7 considered that telehealth added to their home monitoring.
8
9
10
11
12

13
14 No direct comparators to this qualitative study, which examined telemonitoring provided in a usual
15 care context, have been found. The HITS trial¹⁶, which was the context for this study, showed that
16 patients using telemonitoring in their usual primary care setting had a greater reduction in BP than
17 the control group. Patients found the equipment easy to use and the measurements easy to
18 understand. This was similar to experience reported in other studies with effective interventions
19 incorporating telemonitoring such as TASMINT¹³ and differed from a recent US based study
20 where difficulties in using the system were reported³² and the effect was much smaller.¹⁹ System
21 design (hardware, software and the associated guidance and support) clearly has a part to play, and
22 providing the service via the patient's usual practitioners, rather than as a separate stand-alone
23 service, may have also helped in terms of patient support. There is also a possibility that some of the
24 usability issues may be related to the populations involved. In the US study issues with poor literacy
25 were identified³² whereas, although the population for the trial which underpinned this study¹⁶ was
26 drawn from across the spectrum of social privilege and deprivation in Scotland, this was not a
27 concern raised at any point. In some of the trials of larger interventions incorporating BP
28 telemonitoring^{12,18,19}, it is hard to unravel the impact of the telemonitoring from the impact of the
29 rest of the intervention. This study, and the trial outcome, suggests that the telemonitoring itself can
30 overcome some of the barriers to improved BP control. The added value of the additional
31 interventions such as pharmacist support¹² or medication self-management plans¹⁸ needs to be
32 determined. Interestingly, the qualitative study associated with a trial which included telemonitoring
33 and medication self-management suggested that although many participants would be happy to
34 continue with the telemonitoring, few would be happy to continue with the medication self-
35 management plans.¹³
36
37
38

50
51 The consensus amongst the professionals interviewed was that a nurse-led monitoring service would
52 be most appropriate, but some patients perceived that nurses could not prescribe the changes to
53 medication which the patients thought they needed. This could be a limiting factor on the efficiency
54 of the service. The legislative and training framework for independent nurse prescribing has been
55 established in Scotland³³ but the number of nurse prescribers is still very limited, although
56
57
58
59
60

growing.³⁴ Increasing nurse prescribing in long-term conditions may be key to providing the organisational infrastructure to maximize the efficiency of this model of telemonitoring. Integration of the telemonitoring data with electronic patient records would also be essential; patients are free to consult with other members of the primary health care team and expect their BP data to be available. Further consideration needs to be given to the workload issues for the practices involved. The trial did increase their workloads¹⁶, but the discussion group considered that telemonitoring could reduce the need for practice visits in the longer term. This raises the question of whether telemonitoring should be a short or longer term intervention. A model where initial professional surveillance of BP gives way to patient self monitoring once control is established, should be investigated.

In conclusion, this qualitative study indicates that in a UK context BP telemonitoring in a usual care setting can provide a trusted basis for medication management and improved BP control. It increases patients' engagement in the management of their condition, but professional time for supporting telemetry support and greater patient engagement can increase workloads and demand changes in service organisation. However, if these issues are overcome, BP telemonitoring could be an effective tool in the management of hypertension.

Acknowledgements

Thanks are due to the practices and patients who participated in the study, to Lucy McCloughan and Mary Paterson for assistance with organisation, to Hillarie Higgins and Peter Fairbrother for assistance with data analysis. Paul Padfield and Sarah Wild were grant holders and contributed to the overall project. This study was overseen by the Telescot independent steering committee, Professor Sir Lewis Ritchie, Professor Ann-Louise Kinmonth and Professor Chris Griffiths.

Contributions and Declaration

Contributors: Brian McKinstry, Janet Hanley and Claudia Pagliari designed the study. Janet Hanley and Brian McKinstry led the research. Jenny Ure collected the data and led the analysis. Aziz Sheikh provided advice throughout the trial. All authors were involved in writing the paper.

Funding: This study was funded by the BUPA Foundation with additional support from the High Blood pressure Foundation and NHS Lothian. Brian McKinstry and Janet Hanley were during the course of the study supported by the Scottish Chief Scientist Office. The funders had no role in the analysis, writing up of the results or decision to publish. The researchers were independent of the funders.

1 Competing interests: All authors have completed the Unified Competing Interest form

Box 1 Description of the telemonitoring intervention

The intervention

The practices and patients were asked to use a system which comprised a validated electronic home BP monitor and mobile phone technology that enabled the transfer of BP readings via SMS to a secure website which was accessible to the user and their doctor or nurse, and also provided automated feedback to the patient. The BP monitor linked to a mobile phone wirelessly, via Bluetooth. The components of the intervention were:

Home BP monitoring: Patients were asked to record their BP as agreed with the healthcare team, or more frequently as they wished. Guidance was initially to record BP twice in the morning and twice in the evening for a week in line with the European guideline on BP monitoring, to build a baseline average. Thereafter, they were asked to take weekly measurements preferably at different times of day if their average BP was within the recommended range, but if they had made any lifestyle or medication change which would impact on their BP, they were asked to measure their BP for a more intensive period of monitoring to allow the rolling average to change and to more quickly assess the effect.

Transmission of data: This simply required the phone to be switched on and to have a signal when the BP measurement was taken. Patients just had to apply the cuff and press a button on the BP monitor. The reading and transmission occurred automatically. Mobile phone problems did not lead to loss of data because all readings were stored in the monitor and any untransmitted readings were sent when the next reading was taken.

Feedback to patients (closed loop feedback): In addition to optionally accessing their BP record on-line, patients could also opt to receive reports via text message or email. These gave advice on the current status of their BP based on the average of the last 10 readings, and whether they should contact their doctor or nurse. Reports were generated every 10 readings or weekly, whichever was sooner, with a reminder to check BP if this had not been done. These reports could reassure them that their average BP was within target (<135/85mmHg) or tell them that their BP average was improved on the last report but not yet to target and to maintain current therapy, or that their BP was not at target and that they should contact their clinician. If an individual BP reading was very high (>220/120mmHg) an immediate text or email report was generated reinforcing the written advice in the patient information leaflet to rest for 30 minutes, check again and contact the practice if BP remained very high.

Sharing the readings with the healthcare team: Members of the healthcare team were able to access the records of their patients online via a secure login to a summary screen which listed their patients, their average BP over the last 10 readings, and the date of their last reading. Average BPs outside the recommended limits (set at 135/85mmHg for the study) were highlighted. Clicking on the each individual patient led to lists or graphs of all their readings. Clinicians could then check the patients' electronic GP record to see if there had been recent advice regarding medication or lifestyle change and if not, could contact the patient to make a change. Clinicians were recommended to check the website weekly, but the frequency of log-on could be chosen by them.

Usual Care

Patients allocated to the usual care group were asked to continue to attend the practice for BP checks according to the usual routine of the practice. If they were already home monitoring they were not discouraged from continuing.

All patients

For all patients the GP/practice nurse were informed that the ambulatory monitoring used to screen for eligibility for the HITS trial had shown that their average BP was above the target range, but they were not given the actual reading. All patients were given an information pack containing a range of publicly available leaflets on hypertension management and lifestyle modification.

What This Paper Adds

The trial which formed the context for this paper shows that BP telemonitoring integrated into hypertension patients' usual primary care primary care provision can lead to improvements in management. However, it is a complex social intervention and the qualitative literature on BP telemonitoring, which is mainly based on trials where the telemonitoring is only part of a larger intervention, or there is little involvement of the usual care provider, does not explain why telemonitoring in this context is effective, or what may be required for the success of the trial to be translated into routine care.

This study showed that both patients and professionals were reluctant to increase medication based on single BP measurements taken in the surgery. The telemonitoring measurements based on multiple readings were perceived as being more accurate and there was a willingness to act on them. Patients using telemonitoring became more engaged in the management of their condition. Professionals found that telemonitoring increased their workloads, and some changes in working practices were needed to support it effectively.

Abstract

Objectives: To explore the experiences of patients and professionals taking part in a randomised controlled trial (RCT) of remote blood pressure (BP) telemonitoring supported by primary care. To identify factors facilitating or hindering the ~~effectiveness~~ success of the intervention and those likely to influence its potential translation to routine practice.

Design: Qualitative study adopting a qualitative descriptive approach.

Participants: Twenty five patients, 11 nurses and 9 doctors who were participating in an RCT of BP telemonitoring. A maximum variation sample of patients from within the trial based on age, sex, and deprivation status of the practice was sought.

Setting: Six primary care practices in Scotland.

Method: Data were collected via taped semi-structured interviews. Initial thematic analysis was inductive. Multiple strategies were employed to ensure that the analysis was credible and trustworthy.

Results: Prior to the trial both patients and professionals were reluctant to increase medication based on single BP measurements taken in the surgery. BP measurements based on multiple electronic readings were perceived as more accurate as a basis for action. Patients using telemonitoring became more engaged in the clinical management of their condition. Professionals reported that telemonitoring challenged existing roles and work practices and increased workload. Lack of integration of telemonitoring data with the electronic health record (EHR) was perceived as a drawback.

Conclusions: BP telemonitoring in a usual care setting can provide a trusted basis for medication management and improved BP control. It increases patients' engagement in the management of their condition, but supporting telemetry and greater patient engagement can increase professional workloads and demand changes in service organisation. Successful service design in practice would have to take account of how additional roles and responsibilities could be re-aligned with existing work and data management practices

The embedded qualitative study was included in the protocol for the HITS trial registered with ISRCTN no. 72614272.

Summary

Article Focus

- Qualitative exploration of the experiences of patients and professionals taking part in a randomised controlled trial (RCT) of remote blood pressure (BP) telemonitoring supported by primary care.
- Identification of factors facilitating or hindering the success of the intervention and those likely to influence its potential translation to routine practice

Key Messages

- BP telemonitoring in a usual care setting can provide a trusted basis for medication management and improved BP control.
- It increases patients' engagement in the management of their condition,
- Supporting telemonitoring and greater patient engagement can increase professional workloads and demand changes in service organisation.

Strengths and limitations of this study

The strengths of the study are that it is based on experience of using the systems by the patients' own practitioners in a usual care context. The trial context permitted triangulation with quantitative data. Because the protocol permitted evolution in practice, it gives an indication of some of the issues which would need to be addressed for BP telemonitoring to be used in routine practice. The weaknesses are that participation in the study was relatively short for each practice with limited patient numbers so any longer term barriers to evolution in practice were not identified. It is also possible that participants in this study differ from non-participants.

Background

Long term illness is increasingly prevalent and telemonitoring (remote self-monitoring of health parameters with electronic transmission of data to a health care provider) is considered to be a promising way of supporting patient care within existing resources.¹ However, despite policy statements and numerous pilots, telemonitoring has not yet been widely adopted.² This qualitative study examined patient and professional experiences of BP telemonitoring in the context of an RCT. As an embedded qualitative study its purpose was to help explain the trial results and to generate insights regarding factors likely to influence the adoption of this approach within routine care.

Hypertension (persistently raised BP >140/90 mmHg), is a major cardiovascular risk factor, which is frequently poorly controlled,³ with evidence of under treatment in many cases, sometimes described as 'therapeutic inertia'.⁴ This is despite the availability of guidelines^{5,6} or (as in the UK) financial incentives to primary care doctors.⁷ In day-to-day practice effective assessment of BP is problematic. Single BP measurements taken in the surgery are poorer indicators of risk than estimates based on multiple measures from ambulatory or home monitoring^{8,9,10} and 'white coat hypertension' – raised BP when measured in the surgery, but not at home¹¹ – is a complicating factor. However, for practical reasons, surgery-based measurements are still the basis of treatment decision making in most cases. Telemonitoring can overcome these measurement issues by allowing patients to take multiple BP readings at home and share them with healthcare professionals in almost real time, potentially providing motivation for improvements in self-care whilst facilitating professional input if necessary. Although we have been unable to identify previous qualitative studies of telemonitoring in hypertension in a usual care setting, some common themes are emerging from qualitative studies where the self-monitoring was either part of a larger intervention such as specialist nursing support or self-management of medication,^{12,13} or the patients were simply self-monitoring with no data transmission.^{14,15} The common themes were that patients generally find self-monitoring to be a positive experience which is empowering, reassuring and motivational.

The trial which formed the context for this study¹⁶ (see Box 1 for summary of the intervention) involved patients from primary care hypertension registers whose surgery BP measures in the previous 6 months had been > 140/90mmHg, who had a BP higher than 135/85mmHg on daytime ambulatory BP monitoring performed as screening for the trial, and did not have diabetes, previous stroke or transient ischaemic attack, atrial fibrillation or other major illness. ~~It~~ found that for those using telemonitoring, BP reduced by a mean of 4.3/ 2.6 mmHg compared with the group receiving usual care. Other trials in this field also strongly suggest that telemonitoring in hypertension can be effective in achieving clinically important reductions in systolic and diastolic

1
2
3
4
5 BP^{17,18} but some studies have shown poorer outcomes.¹⁹ The introduction of telemonitoring may be
6 regarded as a complex sociotechnical intervention involving changes in behaviour in addition to a
7 purely technological solution. It is therefore important to understand how components of the
8 intervention and contextual factors contribute to the outcome.²⁰ These issues can be difficult to
9 explore using quantitative methods alone²¹ and proponents of 'realist evaluation' suggest using
10 qualitative methods to tease out what works in different contexts.²² The aim of this study, therefore,
11 was to qualitatively explore the experiences of patients and professionals taking part in a trial of BP
12 telemonitoring based in a usual care setting, to identify what contributed to the effectiveness
13 success of the intervention, what limited its effectivenesssuccess and what may be required for the
14 success of the trial to be translated into routine care.

23 Methods

24 Overview

25
26 This study was embedded within an RCT of BP telemonitoring in routine care for patients whose BP
27 was above target^{16,18} (Box 1). ~~Patients who had diabetes or previous stroke or transient ischaemic~~
28 ~~attack were not included as they were asked to take part in separate trials.~~ A qualitative descriptive
29 approach was employed,²³ acknowledging that in health services research the need of the
30 researcher is not simply to provide a description of the phenomenon, but also to produce an
31 interpretive account which will help to guide health care innovation whilst, at the same time,
32 recognising the subjective nature of the encounter between the subject and the researcher.²⁴

37 Ethics and governance considerations

38
39 The study received ethical approval from the South East Scotland Ethics Service (08/S1101/38) and
40 R&D approval from NHS Lothian. Patients were made aware that they may be approached for the
41 embedded qualitative study when they agreed to participate in the trial, but that participation in this
42 study would be optional. Patients and professionals approached were sent a separate information
43 sheet about the qualitative study and signed an additional consent prior to participation.

47 Sampling and recruitment

48
49 Twenty GP practices and 401 patients participated in the RCT. Of these, patients and staff from five
50 socio-economically diverse practices (based on the Scottish Index of Multiple Deprivation²⁵) were
51 initially approached to participate in the qualitative study. A sixth practice was added later to
52 increase the number of professionals participating and ensure data saturation. A maximum
53
54

Formatted: Superscript

1
2
3
4
5 variation patient sample of at least 20 patients overall from these practices was sought based on
6 age, sex, and the deprivation status of the practice. Patients participating in the trial were
7 purposively sampled and checks were made with the practice to ensure that it was still appropriate
8 to approach the patient before they were contacted by letter. Those who did not respond were
9 replaced by patients with similar characteristics. The aim of this sampling strategy was to capture a
10 broad range of patient experiences across the socio-economic spectrum included within the trial.
11
12
13

14 15 16 **Data generation and handling**

17
18 Qualitative data were gathered through semi-structured interviews with patients, nurses and
19 doctors. The initial topic guides were based on issues identified by our previous acceptability
20 study²⁶ and interviews with patients participating in the trial pilot study. The interview topic guides
21 were refined iteratively in response to the initial interviews. The final topic guides are shown in
22 Appendix 1. Most patients were interviewed face-to-face in their own home, and professionals at
23 their workplace, with interviews carried out by telephone where this was not possible. Most
24 healthcare professionals were interviewed individually, but two nurses were interviewed together,
25 as were three doctors. Interviews were carried out by JU, an experienced female qualitative
26 researcher with a background in education and psychology who was not involved in the RCT.
27
28
29
30
31
32
33

34 **Data handling and analysis**

35
36 The data were collected between July 2009 and June 2010 and, with a little variation due to
37 availability, in tranches reflecting different start dates of different practices. Provisional coding and
38 identification of themes took place after each tranche of interviews. Interviewing continued until
39 the researcher, in discussion with the wider research team, considered that data saturation was
40 achieved. Although there is discussion on the concept of data saturation, in the context of this study
41 which was focused and involved a relatively homogeneous population, data saturation was
42 considered to have occurred when the researcher was not identifying any new themes or codes
43 within the provisional themes in sequential interviews, and thought this would be unlikely in
44 subsequent interviews. Detailed re-coding and checking took place from May-December 2010 with
45 the validation focus group taking place in May 2011.
46
47
48
49

50 All interviews were recorded, fully transcribed and the transcript checked against the recording.
51 They were analysed thematically with initial codes and themes identified inductively from the data.
52 Patient and professional data were coded separately. Coding was marked on the transcripts using

8 A range of strategies was employed to ensure that the analysis was credible and trustworthy.
9 Constant comparison was used to ensure consistency in coding and negative cases were sought for
10 each coding category. Coding was checked and iteratively refined using paired analysis of transcripts
11 by two researchers. Researcher reflexivity was supported by discussing emerging findings with the
12 wider research group where different explanations were explored and the coding and thematic
13 analysis reviewed and refined. Following this, the thematic analysis was presented by JH to a
14 discussion group of 21 patients, professionals and researchers who had participated. The
15 presentation introduced the themes and illustrative quotes and the whole dataset (all the text
16 associated with each code) was made available to the participants. This discussion, which lasted for
17 90 minutes, was moderated by BM, recorded, transcribed and coded. It was used to validate the
18 initial grouping of data into codes and themes, but also to extend the discussion of how telehealth
19 may change the provision of primary care. The coding is shown in Appendix 2.
20
21
22
23
24
25

26 The themes were grouped into the four overarching themes presented here. The groupings were
27 broadly informed by the purpose of the study and also by the normalisation process model as
28 applied to telehealth, with its constructs of interactional workability, relational integration, skill set
29 workability and contextual integration²⁷. Appendix 2 shows the codes, (with the number of text
30 extracts coded against each), and how they have been grouped into themes and overarching
31 themes. Where it was possible to triangulate findings arising from the qualitative data against the
32 quantitative trial data (~~including~~ workload impacts, [lifestyle change and the impact of
33 telemonitoring compared with simple home monitoring](#)), this was also done. Three overarching
34 themes are presented here. The fourth theme comprised comments about the study and is shown in
35 Appendix 2.

40
41

42 Results

43 Thirty four patients were approached (28 from the intervention arm and eight from the control arm)
44 and 25 patients (5 from the control arm of the trial) participated. The patient characteristics are
45 shown in Table 1. Eleven practice nurses (all female) and 9 GPs (4 male, 5 female) took part. [Five
46 patients from the control group were interviewed because it was possible that their treatment may
47 have been different than usual during the trial. There was no evidence from the interviews that this
48 had happened.](#)
49
50
51
52

53 The telemonitoring service employed in this study was novel in that self-monitoring was integrated
54 with usual care. For this reason we present the patient and professional data together here,
55
56
57
58
59

highlighting areas of concordance, divergence and evolution in practice both between and within the professional and patient groups.

The Patient Experience

Patients' accounts of their response to the initial diagnosis of hypertension differed, as did their level of concern and their personal approaches to self-management. Some were not concerned, did not think of their hypertension often and left the management to their doctor or nurse. For others the diagnosis had caused practical problems (e.g. in taking out life insurance) or anxiety, particularly where they had experience of a family member suffering a stroke. Anxiety about what was happening to their BP between appointments had led some to self-monitor their BP prior to this study, and one practice provided patients with a home monitor to use during diagnosis. Contrasting perspectives are illustrated in the quotations below.

Oh I just take my tablet. I don't think about it....I'm not the worrying kindI don't see the point in worrying over things.

_____ (Patient 1, control group, previous experience of home monitoring with practice monitor)

And I'm conscious of it because what I'm looking to do you do have to have a medical, and blood pressure is one of the key things that they don't want, if you have high blood pressure you're out. So I'm looking to get it down

_____ (Patient 20, monitoring group, no previous experience of home monitoring)

I can't remember if they...if I was advised to go and buy a home monitoring machine but I decided to do it anyway.....I knew that my blood pressure would be checked every time, regularly at the surgery but certainly twice a year, but until that I would like more information than that.

_____ (Patient 4, control group, previous experience of home monitoring with own monitor)

The differing levels of patient concern about hypertension at the start of the study is clearly a factor which could influence outcomes, but was not something which was directly measured in the trial¹⁶⁴⁶.

~~However, it was possible to compare outcomes between the 30% who self-monitored prior to the trial and those who did not (this analysis not included in the published trial results). Although the results were not statistically significant, there was a trend towards a better outcome with telemetry supported home monitoring for those who had monitored their own BP before the trial compared with those who had never previously used a home monitor. In the telemonitoring group the mean~~

reduction in systolic daytime ambulatory BP for those who had used home monitoring before the trial was 7.16mmHg (95% CI 3.67 to 10.64mmHg) compared to those receiving usual care, but amongst those who had never used home monitoring before the trial, the difference in outcome between those using telemonitoring and the control group in was 2.89 mmHg (95% CI -0.06 to 5.85mmHg). This suggests that patients' concern about their BP was one factor in the success of the intervention. It also suggests that the telemetry and communication with the practice contributed to the outcome rather than just the home monitoring.

Patients saw hypertension largely as a lifestyle issue and many tried to ascribe a cause within their lifestyle such as reduced physical activity and stress, although some also mentioned familial tendency to high BP.

"I wasn't say like grossly overweight, I wasn't...didn't smoke at all, it was difficult to...I mean I did have a more difficult lifestyle at the time, a lot of commuting, a lot of driving"

(Patient 6, monitoring group, no previous experience of home monitoring)

Formatted: Indent: Left: 0.5"

Most were aware that lifestyle change could help control BP and had been given advice. Lifestyle advice was received from multiple sources and perceived to be general rather than being targeted at the reasons for them individually developing hypertension.

"...a proper balanced diet and not too much fat and all these sort of things. But it's strange if anyone doesn't know about that nowadays"

_____(Patient 17, monitoring group, no previous experience of home monitoring,)

Some participants had modified their lifestyle prior to the trial in response to the diagnosis of hypertension

What I did do [when diagnosed with hypertension] and I've stuck to it, I've cut out salt. I was overweight a few years ago and I cut out butter, so now I don't have butter and I don't have salt. (I) just (use) general knowledge, just tried to reduce salt, reduce weight. And salt brings up your blood pressure so...

_____(Patient 12, monitoring group, no previous experience of home monitoring)

Some of the patients interviewed had modified their lifestyle during the trial, and considered that the system provided motivation

"... I had lost a stone in weight during the course of that six months as well that I was being on the monitor and I think that did. I think that was a contributory factor to my BP balancing out"

_____ (Patient 7, monitoring group, previous experience of home monitoring with practice monitor)

"When I was taking the blood pressure I couldn't bear looking at a hundred and forty, a hundred and fifty over a hundred and ten and I wanted to just be able to see better readings in a way. So over the summer as well, starting to get more walking exercise, that kind of thing.... I didn't want beta blockers because they had various side effects which..... I kind of felt the conventional medicine options were maybe a bit limited in terms of what I wanted out of it or in terms of avoiding side effects, so it did spur me on to look for alternative..."

(Patient 2, monitoring group, no previous experience of home monitoring,)

"So I like having the machine there because it prompts me, and I've done things like I've done some exercise and then I've taken my blood pressure to see whether it has made an impact, and it did, it does, every time."

_____ (Patient 20
monitoring group, no previous experience of home monitoring,)

However, many others were aware of the need for lifestyle change but found it too difficult to implement .

"...obviously I'm overweight, I'm trying to do something about that but it just doesn't happen".

_____ (Patient 4, control group, previous experience of home monitoring with own monitor)

The quantitative results of the trial¹⁶⁴⁶ did not show any significant changes to lifestyle variables relating to diet, exercise or medication adherence in either the intervention or control groups. However, closer examination of the trial data did show that in both groups a small number of individuals (10 overall) had, as described by Patient 7, lost more than 1 stone (6.5Kg) in weight.

Using the system increased some patients' engagement with the medical management of their hypertension. They used it to negotiate treatment and, in a very small number of cases, titrate their own medication.

1
2
3
4
5 "It's certainly given me more meaningful data to speak to the doctor rather than, "Well, I
6 think my BP has probably gone up." "

7
8 (Patient 6, monitoring group, no previous experience of home monitoring)

9
10
11
12 "...I've got 16 milligrams and eight milligrams [tablets of antihypertensive drug] and the last
13 time I saw Dr B he said; the maximum you can have is 32. Well what I probably could do is go
14 and see the nurse and say can I take it upon myself to move it up to 32 by taking another
15 eight"

16
17
18
19 _____(Patient 19,
20 monitoring group, no previous experience of home monitoring)

Formatted: English (U.K.)

21
22 These data suggest that the interaction between patient and doctor or nurse facilitated by the
23 telemetry is important rather than just the home monitoring. This is supported by trial data where it
24 was possible to compare outcomes between the telemonitoring group and control group for the
25 30% of patients who had self-monitored prior to the trial (this analysis was not included in the
26 published trial results). Within this group, those randomised to telemonitoring had a mean
27 reduction in systolic daytime ambulatory BP of 7.16mmHg (95% CI 3.67 to 10.64mmHg) compared to
28 those receiving usual care.

29
30
31
32 Generally, both patients and professionals thought the increased patient engagement in BP
33 management was beneficial.

34
35
36
37 "Yes. I really thought that it (system) was a brilliant idea. And it has helped me a lot, to
38 understand more"

39
40 (Patient 6, monitoring group, no previous experience of home monitoring)

41
42
43
44 "...the positive thing about it was it definitely helps patients to become much more involved
45 in their care which is a good thing and they definitely take much more interest in it I think
46 because they're measuring it, they can see it, you know it's much more real to them I think"

47
48 (Practice Nurse 9)

49
50
51 However, a note of caution was sounded, again by both patients and professionals, that for a small
52 number of people home monitoring could provoke anxiety

1
2
3
4
5 *"I felt it was intrusive. I started worrying about my BP"*

6
7 *(Patient 12 monitoring group, no previous experience of home monitoring,)*

8
9
10
11 *"...and then you've got others; 'Oh, I feel a bit ill today, I'll better check my BP'... and I think*
12 *that that's the danger of home monitoring, I think people can become obsessed with it..."*

13
14 *(Practice Nurse 6)*

15
16 Although both patients and professionals raised the issue of anxiety generated by home monitoring,
17 it was a much stronger theme amongst the professionals. It was only raised by one patient during
18 the interviews, but several professionals. This accords with our previous telehealth work where
19 there is considerable concern amongst professional about the possibility of telehealth putting
20 patients in a 'sick role' and making them dependent or anxious, but this concern is not widely
21 echoed by patients^{28, 29}.

22 23 24 25 26 27 **Using the telemonitoring system**

28
29 The simple telemonitoring system used in this study generally worked well, although some design
30 issues were highlighted as described below. Generally, patients had little difficulty measuring their
31 BP, transmitting their readings or finding a routine for measuring their BP. Some also accessed the
32 on-line record of their readings. However, the wording of the automated feedback messages sent by
33 the system to was not found to be valuable although the messages in themselves did remind some
34 patients to maintain their engagement with the system.

35
36 *"it's the same message from presumably a machine [laughs] which doesn't help a lot.*

37
38 *Because it's obviously coming from a machine and it tells me have I contacted my medical*
39 *practice or nurse, which I have but it doesn't seem to know that, you see? "*

40
41
42
43 *(Patient 9, monitoring group, previous experience of home monitoring with practice*
44 *monitor)*

45
46
47 The main clinical advantage provided by the system was that that it facilitated management of BP
48 using average BP, based on multiple readings taken at home, which was seen by both patients and
49 professionals as a more trustworthy basis for action than single BP measurements taken in the
50 surgery. Both patients and professionals commented that, prior to the system being introduced,
51 there were sometimes long delays in initiating appropriate treatment in people with less markedly
52 raised BP, driven by reluctance by healthcare staff to prescribe medication which may not be
53
54
55

absolutely necessary. The data from the patients who were not in the intervention group suggested that, for them, medication changes remained infrequent and this was supported by the trial data¹⁶⁺⁶.

Formatted: Superscript

"[prior to the trial]... you have a BP maybe 148 over 88, you might say 'let's see you again in six months', when actually it's too high" (Practice Nurse 10)

"[prior to the trial] ...We're all guilty of it...'we'll just see how it goes, you know, maybe watch it. I'll check it again tomorrow' and they probably maybe sit on it a bit longer than they...it's just a natural thing isn't it" (Practice Nurse 9)

"...and this patient in particular has been quite reluctant to increase the medication because of her belief that her high BP is just a temporary thing because of what's going on her life...she doesn't think that she should be on medication at all" (Practice Nurse 11)

There was consensus between both patients and professionals that the home monitoring system provided a more accurate assessment of BP than surgery measurements and better evidence for action, facilitating rapid tailoring of medication.

"you're getting a more accurate insight into true BP readings" (Practice Nurse 6)

"Well I tried everything. I had it on the table, I had my arm on a pillow and I was trying to relax as much as I could, but there's no way you're going to cheat the machine so it's... it is a good thing like. You cannot kid yourself on with it"

(Patient 6, monitoring group, no previous experience of home monitoring)

One consequence of the professionals now feeling that they had an ongoing accurate estimate of the patient's average BP was to raise new questions about what to do if it BP was near, but not at, the target.

"The only problem I had with it in a way is these people that were coming up as uncontrolled who were one millimetre above the control level. And I just thought, oh come on, are you really going to add in another drug to bring this down from 81 to 80?"

(GP1)

For healthcare staff the main practical issue with the system was the lack of integration of the BP data with the main patient electronic records and the fact that not all members of the healthcare team regularly accessed the online system and were able to see the patient-recorded readings. This caused problems when patients consulted with other members of the team.

1
2
3
4
5 *"...So they're coming in to see the doctor, the doctor takes their BP, one forty five ninety; 'oh,*
6 *that's fine, what are you worried about?' ... And then you go and you look at it the next*
7 *week and you think; they've seen the doctor and yet their BP's still really high"*
8
9

10 (Practice Nurse 11)

11
12 The trial thus flagged wider implementation issues such as the need for reconfiguration of work
13 practices to accommodate new roles, and ensure synergies across a more distributed care team, as
14 well as more integrated access to patient data from disparate data sources.
15

16 17 18 19 **Adjusting to new responsibilities and new ways of working**

20
21 The new service and increased patient engagement challenged organisation within practices.
22 Professionals reported that monitoring the electronic data, increased patient contact and the need
23 for more rapid decision making raised workloads. The consensus was that a nurse-led service would
24 be the best model, but monitoring the system needed to be an acknowledged part of the practice
25 nurses' role with regular formal time set aside for an electronic clinic. Not all practices succeeded in
26 monitoring the electronic data regularly throughout the trial. The trial data confirmed the increased
27 workload with patients in the telemonitoring group having, on average, two additional consultations
28 with the practice (one with the GP and one with the practice nurse, half of which were by telephone)
29 over the 6 months of the trial compared to the control group.¹⁶⁺⁶
30
31
32

Formatted: Superscript

33
34 Care had traditionally been face- to- face, but continuing to use this model to try to respond quickly
35 to the telemetry data had its frustrations.
36

37
38 *"We would phone them and say your BP's up, we need to increase your medication or you*
39 *need to come in and see someone ... And they never made appointments and then we had to*
40 *phone them again and say 'You've still not made an appointment, are you coming in?'"*
41

42 (Practice Nurse 3)

43
44 Some professionals began to change how they worked, reducing reliance on face-to-face contact
45 with the patients. Telephone contact increased although it was also found to be a time consuming
46 way of reaching patients who were frequently not available during working hours.
47

48
49 *"I feel like I'm phoning these patients all the time. If they can't get them in and you're having*
50 *to leave a message then you're going to have to leave a message in the book to make sure*
51 *they've got the message. You're checking to see if they've picked up a prescription because*
52
53
54
55
56
57
58
59
60

1
2
3
4
5 you're then checking their blood pressure - it's still high - 'Have they taken their medication?'
6 You're phoning them... "

7
8
9 (Practice nurse 4)

10
11
12
13
14
15 There was some experimentation in using email with appropriate safeguards and, although only a
16 small number were involved, this worked well.

17
18 "...I got an email from the doctor every week from the readings and he was able to advise me
19 without me having to visit the doctor.

20
21 (Researcher.... how did you feel about that?)

22
23 Well I was quite happy with that. I thought that was great. It was very time saving for me.

24
25 (Researcher: Ahah. So you find the time saving aspect then very useful?)

26
27 Oh, yes, yes definitely. No effort making appointments, you just got an automatic email
28 every week. They give suggestions and like "Take more of the tablet's. 'Take less of the
29 tablets'" and that's how it went until I got a good reading regularly, good readings".

30
31
32
33
34
35 (Patient 7, monitoring group, previous experience of home monitoring with practice monitor)

36
37 Some patients also changed the way they accessed services because they now knew what they
38 wanted e.g. bypassing the practice nurses and going directly to the GP because they thought the
39 nurse could not prescribe a change in medication.

40
41
42 When the data were presented for validation to a discussion group of patients, professionals and
43 researchers, it is this theme, of adapting to new roles and responsibilities, which dominated the
44 discussion. Echoing the themes presented above, patients in the discussion group emphasised the
45 role of telemetry-enabled home monitoring as being motivating, an incentive to improve self-care
46 and evidence which facilitated meaningful conversation and dialogue with professionals. However,
47 despite having been presented with the qualitative data on increased professional workloads and
48 contact with patients (the figures from the trial were not available at that point), they thought that
49 in the longer term home monitoring should lead to a reduction in the need for surgery attendance
50 which would be appreciated by patients. The need for clarity in roles (what the patient was
51
52
53
54
55
56
57
58
59
60

1
2
3
4
5 expected to do and what the practice was expected to do) was emphasised.
6
7
8

9 10 Discussion

11 Both patients and clinicians participating in this study considered that a measurement based on the
12 average of multiple readings from the home monitoring system was trustworthy and could be used
13 as a basis for action. Although patients generally saw hypertension as a lifestyle issue and were
14 aware of lifestyle interventions, only a few achieved significant lifestyle changes during the trial and
15 some were from the control group. However, the system was described by patients as a motivator
16 to achieve BP control and the instantly available, shared and trusted reading facilitated more rapid
17 tailoring of medication. This was partially driven by patients who increased their engagement with
18 the medical management of their condition, initiating contacts and negotiating treatment, and
19 partially by the healthcare professionals who contacted people with unsatisfactory readings. The
20 cost to the practices of achieving improved BP control was increased patient contacts and workloads
21 for professionals during the trial (where all participants had uncontrolled BP at the start). However,
22 when this outcome was discussed with patients and professionals they expressed the view that in
23 the longer term the system could reduce the need for surgery visits. There was an example of this
24 where one patient described asynchronous communication with the practice in the form of email
25 which resulted in tailoring of medication without the need for frequent phone calls and surgery
26 visits.
27
28
29
30
31
32
33
34

35 Prior to the intervention, patients differed in their levels of concern about their hypertension and
36 there was an acknowledgement not all patients would respond to telemonitoring in the same
37 way and some already owned home monitors and there was a trend within the trial data for those
38 who already used home monitors to show greater improvement in their BP. This is consistent with
39 the health beliefs model of behaviour³⁰ where perceived severity of the condition is one of the
40 factors influencing health behaviour.—Some clinicians were concerned that, for a small number of
41 people, monitoring and increased engagement in the medical management of their hypertension
42 may have provoked anxiety or dependency. This was echoed by one patient although generally
43 increased engagement seen to be a positive change by both patients and clinicians.
44
45
46
47
48

49 Within the practices, doctors and nurses found that traditional ways of working, which prioritises
50 face to face consultations and where there may be split responsibilities for BP monitoring and anti-
51 hypertensive prescribing, may not easily support the increased patient engagement or rapid
52 treatment adjustment that successful telemonitoring requires and there was some evolution of
53
54
55
56
57
58
59
60

1
2
3
4
5 working practices during the study. A lack of integration of telemonitoring data with the patients'
6 electronic records also limited multi-disciplinary working within the practices. The acceptance by
7 professionals that they had an accurate estimate of the patients' BP raised questions about the best
8 management when BP was near the recommended level which was not covered in the guidelines
9 available at the time.
10
11

12
13 The strengths of the study are that it is based on real experience of using the systems and, because
14 the protocol permitted evolution in practice, it gives an indication of some of the issues which would
15 need to be addressed for BP telemonitoring to be used in routine practice. These include integrating
16 of telemonitoring data with the electronic patient record, enabling communication channels
17 between patients and professionals which are rapid and efficient for both, implementing inter-
18 professional working practices which support rapid tailoring of medication and additional clinical
19 guidance. The review by Mair et al³¹ on factors affecting the success of telehealth implementations
20 chimes with many of these, as do earlier qualitative studies such as May et al³². Feedback from
21 participants and triangulation with trial data add weight to these interpretations. However, practices
22 were only involved in the trial for a short period (about 8 months) and evolution of practice to meet
23 the needs of patients who are telemonitoring could be limited by factors which have not yet been
24 identified. It is also possible that both patients and practices who agree to participate in a trial may
25 differ in some way from those who choose not to participate, and thus not all opinions about
26 telemonitoring may have been captured. A request to seek opinions about telemonitoring from
27 those who did not want to participate in the trial was declined by the Ethics Committee. A weakness
28 of the study was that triangulation data showing the effectiveness of the intervention amongst those
29 who already owned a home monitor was only received after the end of data collection and the
30 opportunity was lost to interview more of this group and more systematically investigate what they
31 considered that telehealth added to their home monitoring.
32
33

34
35 No direct comparators to this qualitative study, which examined telemonitoring provided in a usual
36 care context, have been found. The HITS trial¹⁶⁴⁶, which was the context for this study, showed that
37 patients using telemonitoring in their usual primary care setting had a greater reduction in BP than
38 the control group. Patients found the equipment easy to use and the measurements easy to
39 understand. This was similar to experience reported in other studies with effective interventions
40 incorporating telemonitoring such as TASMINH2¹³⁴³ and differed from a recent US based study
41 where difficulties in using the system were reported¹⁹⁴⁸ and the effect was much smaller.¹⁹⁴⁸ System
42 design (hardware, software and the associated guidance and support) clearly has a part to play, and
43 providing the service via the patient's usual practitioners, rather than as a separate stand-alone
44 service, may have also helped in terms of patient support. There is also a possibility that some of the

Formatted: Font: (Default) Calibri, 11 pt, English (U.S.), Superscript

usability issues may be related to the populations involved. In the US study issues with poor literacy were identified³³²⁸ whereas, although the population for the trial which underpinned this study¹⁶⁴⁶ was drawn from across the spectrum of social privilege and deprivation in Scotland, this was not a concern raised at any point. In some of the trials of larger interventions incorporating BP telemonitoring^{1242, 1847, 1948}, it is hard to unravel the impact of the telemonitoring from the impact of the rest of the intervention. This study, and the trial outcome, suggests that the telemonitoring itself can overcome some of the barriers to improved BP control. The added value of the additional interventions such as pharmacist support¹² or medication self-management plans¹⁸⁴⁷ needs to be determined. Interestingly, the qualitative study associated with a trial which included telemonitoring and medication self-management suggested that although many participants would be happy to continue with the telemonitoring, few would be happy to continue with the medication self-management plans.¹³¹³

The consensus amongst the professionals interviewed was that a nurse-led monitoring service would be most appropriate, but some patients perceived that nurses could not prescribe the changes to medication which the patients thought they needed. This could be a limiting factor on the efficiency of the service. The legislative and training framework for independent nurse prescribing has been established in Scotland³⁴ but the number of nurse prescribers is still very limited, although growing.³⁵ Increasing nurse prescribing in long-term conditions may be key to providing the organisational infrastructure to maximize the efficiency of this model of telemonitoring. Integration of the telemonitoring data with electronic patient records would also be essential; patients are free to consult with other members of the primary health care team and expect their BP data to be available. Further consideration needs to be given to the workload issues for the practices involved. The trial did increase their workloads¹⁶⁴⁶, but the discussion group considered that telemonitoring could reduce the need for practice visits in the longer term. This raises the question of whether telemonitoring should be a short or longer term intervention. A model where initial professional surveillance of BP gives way to patient self monitoring once control is established, should be investigated.

In conclusion, this qualitative study indicates that in a UK context BP telemonitoring in a usual care setting can provide a trusted basis for medication management and improved BP control. It increases patients' engagement in the management of their condition, but professional time for supporting telemetry support and greater patient engagement can increase workloads and demand changes in service organisation. However, if these issues are overcome, BP telemonitoring could be an effective tool in the management of hypertension.

Acknowledgements

Thanks are due to the practices and patients who participated in the study, to Lucy McCloughan and Mary Paterson for assistance with organisation, to Hillarie Higgins and Peter Fairbrother for assistance with data analysis. Paul Padfield and Sarah Wild were grant holders and contributed to the overall project. This study was overseen by the Telescot independent steering committee, Professor Sir Lewis Ritchie, Professor Ann-Louise Kinmonth and Professor Chris Griffiths.

Contributions and Declaration

Contributors: Brian McKinstry, Janet Hanley and Claudia Pagliari designed the study. Janet Hanley and Brian McKinstry led the research. Jenny Ure collected the data and led the analysis. Aziz Sheikh provided advice throughout the trial. All authors were involved in writing the paper.

Funding: This study was funded by the BUPA Foundation with additional support from the High Blood pressure Foundation and NHS Lothian. Brian McKinstry and Janet Hanley were during the course of the study supported by the Scottish Chief Scientist Office. The funders had no role in the analysis, writing up of the results or decision to publish. The researchers were independent of the funders.

Competing interests: All authors have completed the Unified Competing Interest form at www.icmje.org/coi_disclosure.pdf (available on request from the corresponding author) and declare: no support from any organisation for the submitted work; no financial relationships with any organisations that might have an interest in the submitted work in the previous 3 years; no other relationships or activities that could appear to have influenced the submitted work

All authors had full access to all of the data in the study and can take responsibility for the integrity of the data and the accuracy of the data analysis.

Box 1 Description of the telemonitoring intervention**The intervention**

The practices and patients were asked to use a system which comprised a validated electronic home BP monitor and mobile phone technology that enabled the transfer of BP readings via SMS to a secure website which was accessible to the user and their doctor or nurse, and also provided automated feedback to the patient. The BP monitor linked to a mobile phone wirelessly, via Bluetooth. The components of the intervention were:

Home BP monitoring: Patients were asked to record their BP as agreed with the healthcare team, or more frequently as they wished. Guidance was initially to record BP twice in the morning and twice in the evening for a week in line with the European guideline on BP monitoring, to build a baseline average. Thereafter, they were asked to take weekly measurements preferably at different times of day if their average BP was within the recommended range, but if they had made any lifestyle or medication change which would impact on their BP, they were asked to measure their BP for a more intensive period of monitoring to allow the rolling average to change and to more quickly assess the effect.

Transmission of data: This simply required the phone to be switched on and to have a signal when the BP measurement was taken. Patients just had to apply the cuff and press a button on the BP monitor. The reading and transmission occurred automatically. Mobile phone problems did not lead to loss of data because all readings were stored in the monitor and any untransmitted readings were sent when the next reading was taken.

Feedback to patients (closed loop feedback): In addition to optionally accessing their BP record on-line, patients could also opt to receive reports via text message or email. These gave advice on the current status of their BP based on the average of the last 10 readings, and whether they should contact their doctor or nurse. Reports were generated every 10 readings or weekly, whichever was sooner, with a reminder to check BP if this had not been done. These reports could reassure them that their average BP was within target (<135/85mmHg) or tell them that their BP average was improved on the last report but not yet to target and to maintain current therapy, or that their BP was not at target and that they should contact their clinician. If an individual BP reading was very high (>220/120mmHg) an immediate text or email report was generated reinforcing the written advice in the patient information leaflet to rest for 30 minutes, check again and contact the practice if BP remained very high.

Sharing the readings with the healthcare team: Members of the healthcare team were able to access the records of their patients online via a secure login to a summary screen which listed their patients, their average BP over the last 10 readings, and the date of their last reading. Average BPs outside the recommended limits (set at 135/85mmHg for the study) were highlighted. Clicking on the each individual patient led to lists or graphs of all their readings. Clinicians could then check the patients' electronic GP record to see if there had been recent advice regarding medication or lifestyle change and if not, could contact the patient to make a change. Clinicians were recommended to check the website weekly, but the frequency of log-on could be chosen by them.

Usual Care

Patients allocated to the usual care group were asked to continue to attend the practice for BP checks according to the usual routine of the practice. If they were already home monitoring they were not discouraged from continuing.

All patients

For all patients the GP/practice nurse were informed that the ambulatory monitoring used to screen for eligibility for the HITS trial had shown that their average BP was above the target range, but they were not given the actual reading. All patients were given an information pack containing a range of publicly available leaflets on hypertension management and lifestyle modification.

What This Paper Adds

The trial which formed the context for this paper shows that BP telemonitoring integrated into hypertension patients' usual primary care primary care provision can lead to improvements in management. However, it is a complex social intervention and the qualitative literature on BP telemonitoring, which is mainly based on trials where the telemonitoring is only part of a larger intervention, or there is little involvement of the usual care provider, does not explain why telemonitoring in this context is effective, or what may be required for the success of the trial to be translated into routine care.

This study showed that both patients and professionals were reluctant to increase medication based on single BP measurements taken in the surgery. The telemonitoring measurements based on multiple readings were perceived as being more accurate and there was a willingness to act on them. Patients using telemonitoring became more engaged in the management of their condition. Professionals found that telemonitoring increased their workloads, and some changes in working practices were needed to support it effectively.

Table1. Patient details

Patient	Sex		Age			Group		Deprivation level of practice

APPENDIX 1: Topic Guides for interviews with the healthcare team and patients

Nurse/GP Topic Guide v2.

Experience of using the system

- how they use it/ find it?
- day to day management
- problems/concerns
- technical issues?
- clinical issues?
- organisational issues?

Impact on how BP managed by care team

- has it changed management of BP
- communication with care team
- changes to medication
- adherence to treatment regime
- impact of feedback
- workload
- re-organisation

Impact on how BP managed by patients

- how they use it
- changes in way they see /manage their condition
- anxiety / reassurance/ control/passive/active/self-care
- impact of feedback on
- medicalisation (e.g. some patients found the monitoring made them focus too much on being ill, and not enough on being well)

Implications for use in practice

Patient Topic Guide + Prompts v.2

Non-monitored and Monitored Groups

Experience of the screening process

- own monitor?
- impact?

How they manage their BP / feel about managing it

- day to day management
- do they comply or not with advice and if so why / why not
- anxiety
- adherence to regime/lifestyle and drug tmnt
- sense of control
- have they changed the way they see /manage their condition/if so why

Experience of managing BP with monitor/ without monitor

- technical
- clinical
- personal (anxiety; reassurance)
- organisational

What advice given

- what did they think of advice given
- other factors in lifestyle that might affect this
- what were they told by GP or nurse / what did they understand? do they see it differently?
- do they feel that suggestions are not appropriate for them? Why?

Have views of/ approaches to management changed since first diagnosis / if so why

- information/advice
- readings
- opportunities to change
- other factors – e.g. life events, illness, GP advice

How they feel about it / want to deal with it

- 1
- 2
- 3
- 4
- 5 impact on lifestyle
- 6 sense of control / anxiety/ reassurance
- 7 inconvenience
- 8 **Additional Themes for Monitored group**
- 9 Describe how they use it in practice
- 10 Experience of how nurse/doctor has used it
- 11 Perceived impact?
- 12 onQoL?
- 13 on seeking help?
- 14 on care
- 15 onself care/self management?
- 16 facilitate passive or active control
- 17 on understanding of BP
- 18 on communication with care team
- 19 on appointments.
- 20 Perceived benefits
- 21 Perceived problems
- 22 Which groups would benefit from it in particular?
- 23
- 24

Appendix 2 Themes/subthemes

The thematic headings are derived from the indicator codes.

Overarching Theme	Themes/subthemes :patient interviews	Themes/ subthemes: Nurses and doctors	Themes/ subthemes: Discussion group
The patient experience	<p>The frequency of occurrence of codes is given as a number *Coded to more than 1 theme</p> <p>Diagnosis (Routine check up / out of the blue 4,Diagnosis in relation to other study 1) Perceptions of causes / triggers for high bp (Stress/work stress 4, Weight/lack of exercise 2, Genetics 1, Smoking 2) Experience of care (Positive perception of usual care 5, Advice (helpful/vague/negative/excessive) 6, Organisation of medication 3*) (also coded as more rapid organisation of medication in using the system) Impact (of diagnosis) on self care/ lifestyle 26 (Carried on as usual/ BP checks/ medication 12,Trigger for Change In Lifestyle 7(Starting to/trying to make changes 5,impact on work prospects motivate change2,medication routine 3,complies with medication/ self monitors due to fear of stroke 4),Barriers to lifestyle changes 3 (Other conditions 1, Hard to find the motivation 1, Knowing what but not how 1)) Greater awareness 24 (Greater awareness/ greater acceptance of problem 4*,Readings prompt /challenge/ reinforce change 3*,Basis for understanding own patterns/ causes in own lifestyle 8*,Awareness of variation in context</p>	<p>The frequency of occurrence of codes is given as a number, in brackets the number of interviews in which it occurred, and an indication of how many of these were with a nurse or a GP.</p> <p>Concerns about medication/ putting off taking action 8 (1GP3N) Patient compliance (Barriers (to compliance)13 (2GP7N), General lack of compliance in patients 3(1GP 2N),Other issues a priority 1N,lack of Motivation 1(1N),Compliance tails off 1N,General (Work, Holiday) 3(1GP2N)) Readings/monitoring help patient buy in to treatment 12 (3GP4N) Positive patient experience 7(2gp2n) (Patient Perception of Better Service 2(2GP),They like it/like being monitored 3(1gp1N,)They USE it 1(1GP),They avoid unnecessary visits to GP 2(1GP1N),Good outcomes for patients 1(1N)) Readings prompt/empower patients to take a more active role 14(3gp3n) Readings can provide reinforcement (1N) Readings /reminders can generate anxiety 9(1GP3N)</p>	<p>Perceptions of tele monitoring (For self (IT not reqd),For others (IT reqd.)) Telemonitoring as incentive (Somebody watching, Motivating in sense that data is being looked at, Sense of obligation, Enhances compliance, Poor TM compliance can be flag for non-compliance in other areas (medic.),Example of compliance that led to control, and subsequent reduction in drugs) T.monitoring as evidence (Evidence facilitates meaningful conversation and dialogue)</p>

R Relevance of study question

To explore the experiences of patients and professionals taking part in a randomised controlled trial (RCT) of remote blood pressure (BP) telemonitoring supported by primary care. To identify factors facilitating or hindering the success of the intervention and those likely to influence its potential translation to routine practice.

A Appropriateness of qualitative method

Qualitative study adopting a qualitative descriptive approach

T Transparency of procedures

Sampling

Is the sampling strategy appropriate?

Twenty five patients, 11 nurses and 9 doctors who were participating in an RCT of BP telemonitoring. A maximum variation sample of patients based on age, sex, and deprivation status of the practice was sought.

Recruitment

Was recruitment conducted using appropriate methods?

Patients participating in the trial were purposively sampled and checks were made with the practice to ensure that it was still appropriate to approach the patient before they were contacted by letter. Those who did not respond were replaced by patients with similar characteristics.

Is the sampling strategy appropriate?

Could there be selection bias?

Thirty four patients were approached (28 from the intervention arm and eight from the control arm) and 25 patients (5 from the control arm of the trial) participated.

The patient characteristics are shown in Table 1. Eleven practice nurses (all female) and 9 GPs (4 male, 5 female) took part. Non-participation in the interviews was mainly due to difficulty in arranging a suitable time

Data collection

Was collection of data systematic and comprehensive?

Interview guide provided

Are characteristics of the study group and setting clear?

Table 1 gives description of each patient

Why and when was data collection stopped, and is this reasonable?

Data saturation

Role of researchers

Is the researcher(s) appropriate? How might they bias (good and bad) the conduct of the study and results?

Interviews were carried out by JU, an experienced female qualitative researcher with a background in education and psychology who was not involved in the RCT

Ethics

Was informed consent sought and granted?

Patients were made aware that they may be approached for the embedded qualitative study when they agreed to participate in the trial, but that participation in this study would be optional. Patients and professionals approached were sent a separate information sheet about the qualitative study and signed an additional consent prior to participation

Were participants' anonymity and confidentiality ensured?

Patients identified by number

Was approval from an appropriate ethics committee received?

The study received ethical approval from the South East Scotland Ethics Service (08/S1101/38) and R&D approval from NHS Lothian.

S Soundness of interpretive approach

Analysis

Is the type of analysis appropriate for the type of study?

- *thematic*: exploratory, descriptive, hypothesis generating
 - *framework*: e.g., policy
- *constant comparison/grounded theory*: theory generating, analytical
 -

Are the interpretations clearly presented and adequately supported by the evidence?

Are quotes used and are these appropriate and effective?

Was trustworthiness/reliability of the data and interpretations checked?

All interviews were recorded, fully transcribed and the transcript checked against the recording. They were analysed thematically with initial codes and themes identified inductively from the data.

Appendix 2 shows the codes, (with the number of text extracts coded against each), and how they have been grouped into themes and overarching themes.

Constant comparison was used to ensure consistency in coding and negative cases were sought for each coding category. Coding was checked and iteratively refined using paired analysis of transcripts by two researchers. Researcher reflexivity was supported by discussing emerging findings with the wider research group where different explanations were explored and the coding and thematic analysis

reviewed and refined. Following this, the thematic analysis was presented by JH to a discussion group of 21 patients, professionals and researchers who had participated. The presentation introduced the themes and illustrative quotes and the whole dataset (all the text associated with each code) was made available to the participants. Where it was possible to triangulate findings arising from the qualitative data against the quantitative trial data (eg workload impacts), this was also done

Discussion and presentation

Are findings sufficiently grounded in a theoretical or conceptual framework?	The themes were grouped into the four overarching themes presented here. The groupings were broadly informed by the purpose of the study and also by the normalisation process
Is adequate account taken of previous knowledge and how the findings add?	model as applied to telehealth, with its constructs of interactional workability, relational integration, skill set workability and contextual integration. Additional theoretical perspectives are considered in the discussion
Are the limitations thoughtfully considered?	Strengths and limitations explicitly described and discussed
Is the manuscript well written and accessible?	

Are red flags present? These are common features of ill-conceived or poorly executed qualitative studies, are a cause for concern, and must be viewed critically. They might be fatal flaws, or they may result from lack of detail or clarity.

1 **APPENDIX 1: Topic Guides for interviews with the healthcare team and patients**

2
3 **Nurse/GP Topic Guide v2.**

4 Experience of using the system

- 5
6
7
8
9
10
11
12
- how they use it/ find it?
 - day to day management
 - problems/concerns
 - technical issues?
 - clinical issues?
 - organisational issues?

13 Impact on how BP managed by care team

- 14
15
16
17
18
19
20
21
22
- has it changed management of BP
 - communication with care team
 - changes to medication
 - adherence to treatment regime
 - impact of feedback
 - workload
 - re-organisation

23 Impact on how BP managed by patients

- 24
25
26
27
28
29
30
31
- how they use it
 - changes in way they see /manage their condition
 - anxiety / reassurance/ control/passive/active/self-care
 - impact of feedback on
 - medicalisation (e.g. some patients found the monitoring made them focus too much on being ill, and not enough on being well)

32 Implications for use in practice

33 **Patient Topic Guide + Prompts v.2**

34 **Non-monitored and Monitored Groups**

35 Experience of the screening process

- 36
37
- own monitor?
 - impact?

38 How they manage their BP / feel about managing it

- 39
40
41
42
43
44
45
- day to day management
 - do they comply or not with advice and if so why / why not
 - anxiety
 - adherence to regime/lifestyle and drug tmnt
 - sense of control
 - have they changed the way they see /manage their condition/if so why

46 Experience of managing BP with monitor/ without monitor

- 47
48
49
50
- technical
 - clinical
 - personal (anxiety; reassurance)
 - organisational

51 What advice given

- 52
53
54
55
- what did they think of advice given
 - other factors in lifestyle that might affect this
 - what were they told by GP or nurse / what did they understand? do they see it differently?
 - do they feel that suggestions are not appropriate for them? Why?

56 Have views of/ approaches to management changed since first diagnosis / if so why

- 57
58
59
60
- information/advice
 - readings
 - opportunities to change
 - other factors – e.g. life events, illness, GP advice

How they feel about it / want to deal with it

1 impact on lifestyle
2 sense of control / anxiety/ reassurance
3 inconvenience
4

5 **Additional Themes for Monitored group**

6 Describe how they use it in practice

7 Experience of how nurse/doctor has used it

8 Perceived impact?

9 onQoL?

10 on seeking help?

11 on care

12 onself care/self management?

13 facilitate passive or active control

14 on understanding of BP

15 on communication with care team

16 on appointments.

17 Perceived benefits

18 Perceived problems

19 Which groups would benefit from it in particular?

Appendix 2 Themes/subthemes

The thematic headings are derived from the indicator codes.

Overarching Theme	Themes/subthemes :patient interviews	Themes/ subthemes: Nurses and doctors	Themes/ subthemes: Discussion group
The patient experience	<p>The frequency of occurrence of codes is given as a number *Coded to more than 1 theme</p> <p>Diagnosis (Routine check up / out of the blue 4,Diagnosis in relation to other study 1) Perceptions of causes / triggers for high bp (Stress/work stress 4, Weight/lack of exercise 2, Genetics 1, Smoking 2) Experience of care (Positive perception of usual care 5, Advice (helpful/vague/negative/excessive) 6, Organisation of medication 3*) (also coded as more rapid organisation of medication in using the system) Impact (of diagnosis) on self care/ lifestyle 26 (Carried on as usual/ BP checks/ medication 12, Trigger for Change In Lifestyle 7(Starting to/trying to make changes 5, impact on work prospects motivate change 2, medication routine 3, complies with medication/ self monitors due to fear of stroke 4), Barriers to lifestyle changes 3 (Other conditions 1, Hard to find the motivation 1, Knowing what but not how 1)) Greater awareness 24 (Greater awareness/ greater acceptance of problem 4*, Readings prompt /challenge/ reinforce change 3*, Basis for understanding own patterns/ causes in own lifestyle 8*, Awareness of variation in context</p>	<p>The frequency of occurrence of codes is given as a number, in brackets the number of interviews in which it occurred, and an indication of how many of these were with a nurse or a GP.</p> <p>Concerns about medication/ putting off taking action 8 (1GP3N) Patient compliance (Barriers (to compliance) 13 (2GP7N), General lack of compliance in patients 3(1GP 2N), Other issues a priority 1N, lack of Motivation 1(1N), Compliance tails off 1N, General (Work, Holiday) 3(1GP2N)) Readings/monitoring help patient buy in to treatment 12 (3GP4N) Positive patient experience 7(2gp2n) (Patient Perception of Better Service 2(2GP), They like it/like being monitored 3(1gp1N,) They USE it 1(1GP), They avoid unnecessary visits to GP 2(1GP1N), Good outcomes for patients 1(1N)) Readings prompt/empower patients to take a more active role 14(3gp3n) Readings can provide reinforcement (1N) Readings /reminders can generate anxiety 9(1GP3N)</p>	<p>Perceptions of tele monitoring (For self (IT not reqd), For others (IT reqd.)) Telemonitoring as incentive (Somebody watching, Motivating in sense that data is being looked at, Sense of obligation, Enhances compliance, Poor TM compliance can be flag for non-compliance in other areas (medic.), Example of compliance that led to control, and subsequent reduction in drugs) T.monitoring as evidence (Evidence facilitates meaningful conversation and dialogue)</p>
