## 1. Experimental Section

### A. Kinetic isotope effects (KIEs) and transition state (TS) geometry

Kinetic isotope effect measurements are powerful mechanistic probes. Figure S1 is a 2D representation of the vibrational normal modes associated with the reactant and the transition state for a reaction, focusing on as an example the stretching vibration of a C-H bond. Isotopic substitution, in this case by deuterium, affects the zero-point energy (ZPE) of the vibrational normal modes of a molecule. The main origin of KIEs lies in how the ZPE is different at the stage of reactants versus the transition state. When the normal modes are looser at the transition state versus the starting material, as is most common, the ZPE is decreased and lighter isotopes encounter a smaller barrier. As a result, lighter isotopes tend to react faster ( $k_{\text{light}} / k_{\text{heavy}} > 1$ ) and this observation is referred to as a “normal” isotope effect. Sometimes the normal modes are tighter at the transition state versus the starting material; this causes the ZPE to be increased at the transition state and heavier isotopes encounter a lower barrier. The resulting faster rate for the heavier isotope ( $k_{\text{light}} / k_{\text{heavy}} < 1$ ) is an “inverse” isotope effect. Since the KIEs are intimately associated with the normal modes at the transition state, KIEs can be used to experimentally probe the transition state geometry, i.e. the extent of bond formation / bond breaking occurring as the reaction goes over the transition state.

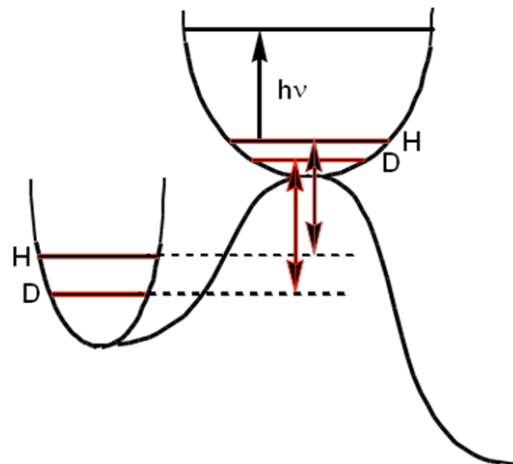

Figure S1. The origin of a kinetic isotope effect

## B. The Singleton method for determining KIEs using natural abundance $^{13}\text{C}$ NMR

Each individual carbon and hydrogen in an organic molecule contains at natural abundance approximately 1.1% of  $^{13}\text{C}$  and 0.015% of  $^2\text{H}$ . As a reaction progresses, the starting materials are enriched in the slower reacting isotopomers (isotopically substituted isomers) and the products in the faster reacting ones. If this isotopic enrichment at every position in a molecule can be measured, KIEs can be determined without the use of explicitly labeled substrate. The Singleton method applies this idea to determine  $^{13}\text{C}$  and  $^2\text{H}$  KIEs at natural abundance using carefully acquired NMR as a method to determine these isotopic compositions. There are two main strategies that can be used for the determination of KIEs using this methodology.

(a) *Intermolecular starting material KIEs* – The original methodology developed in the Singleton group measured KIEs by analysis of starting material recovered from reactions taken to high conversion, typically ~80%. The isotopic composition of this recovered material is determined by NMR at natural abundance and compared to that of unreacted starting material (drawn from the bottle originally used for the reaction). The enrichment (depletion) thus measured can be used to determine the KIEs based on eq 1, where  $F_1$  is the fractional conversion of the lighter isotopomer and  $R/R_0$  is the proportion of minor isotopic component in recovered starting material versus the original material.

$$\frac{\log(1-F_1)}{\log[(1-F_1)(R/R_0)]} \quad (1)$$

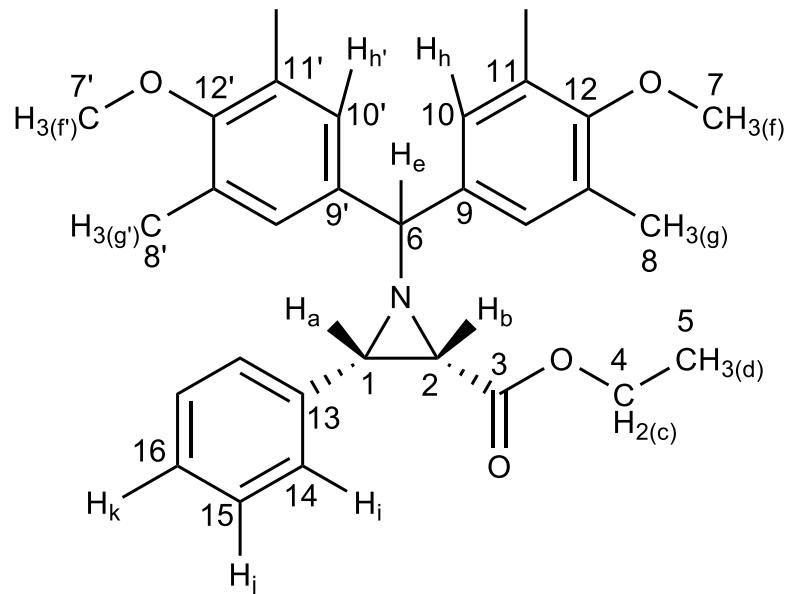

This methodology has some advantages when it can be applied. One advantage is that the precision of the KIEs obtained can exceed the precision of the analysis. Another advantage is that the KIEs are insensitive to further side reactions that the product may undergo. A disadvantage is that the methodology cannot be applied to reactants that must be used in large excess.

- (b) *Intermolecular product KIEs* – An alternative process involves taking reactions to low conversion (typically ~20%) and analyzing the isolated reaction product. The isotopic composition of the product, enriched in the faster reacting isotope, is compared to that of product isolated from a reaction taken to 100% conversion reaction (no isotopic fractionation). Equation 2 is then used to calculate the KIEs. This method is prone to two possible errors.

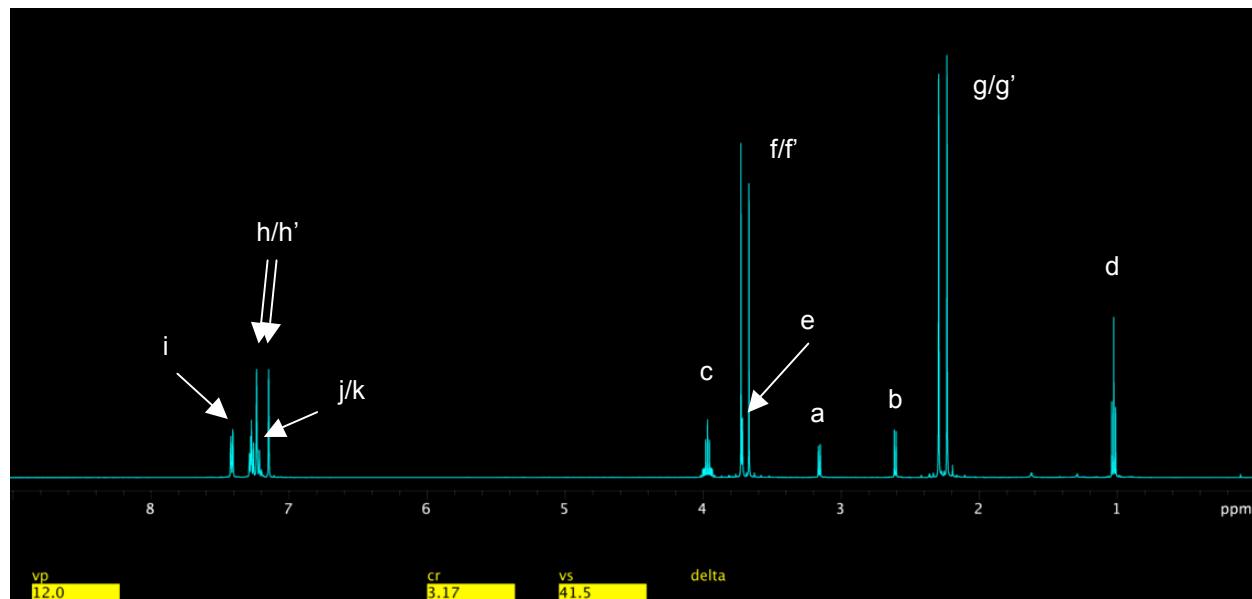

$$\frac{\log(1-F_1)}{\log[1-(F_1R_p/R_o)]} \quad (2)$$

Further conversion of product to form side product will adversely affect the measurement. Also, errors may arise from any inefficiency in the 100% conversion reaction. The subtle modification of this methodology described in this work was originally developed by MJV during his graduate studies in the Singleton group. This modification is time-efficient and accurate, especially for reactions where it is required to determine KIEs for both reactants in a bimolecular reaction. In such cases separate low conversion and 100% conversion reactions are usually performed for each reactant (total 4 reactions for one KIE experiment) in order to ensure accurate determination of fractional conversion, since 1:1 mixtures of starting materials rarely give quantitative yields of product. By using this modified methodology, we eliminate the 100% conversion reactions (thereby getting the same information from 2 reactions instead of 4 reactions) by performing the low conversion reaction for each reactant using limiting amounts (0.2 eq to get to 20% conversion) of the other. Under these conditions, the limiting reagent in both reactions undergo no isotopic fractionation upon going from starting material to product and hence serve as the 100% sample for the complementary reaction.

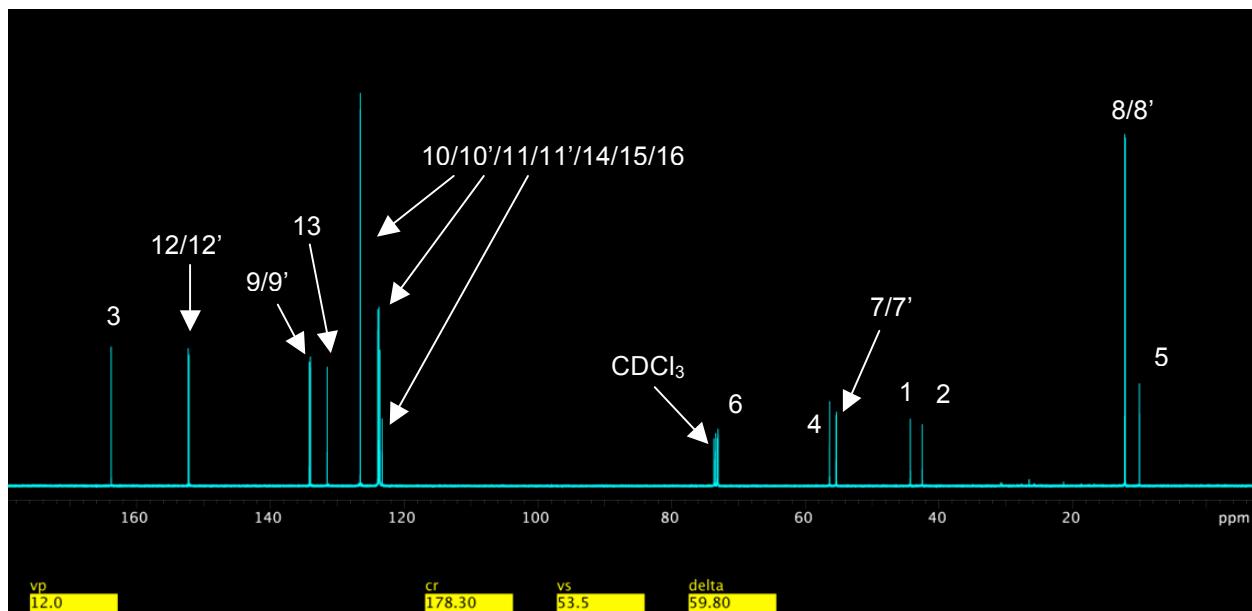

**C. Complete structural assignment of **4a**,  $^1\text{H}$  NMR and  $^{13}\text{C}$  NMR spectra for a representative KIE experiment, and 2D (HMQC and HMBC) NMR spectra**

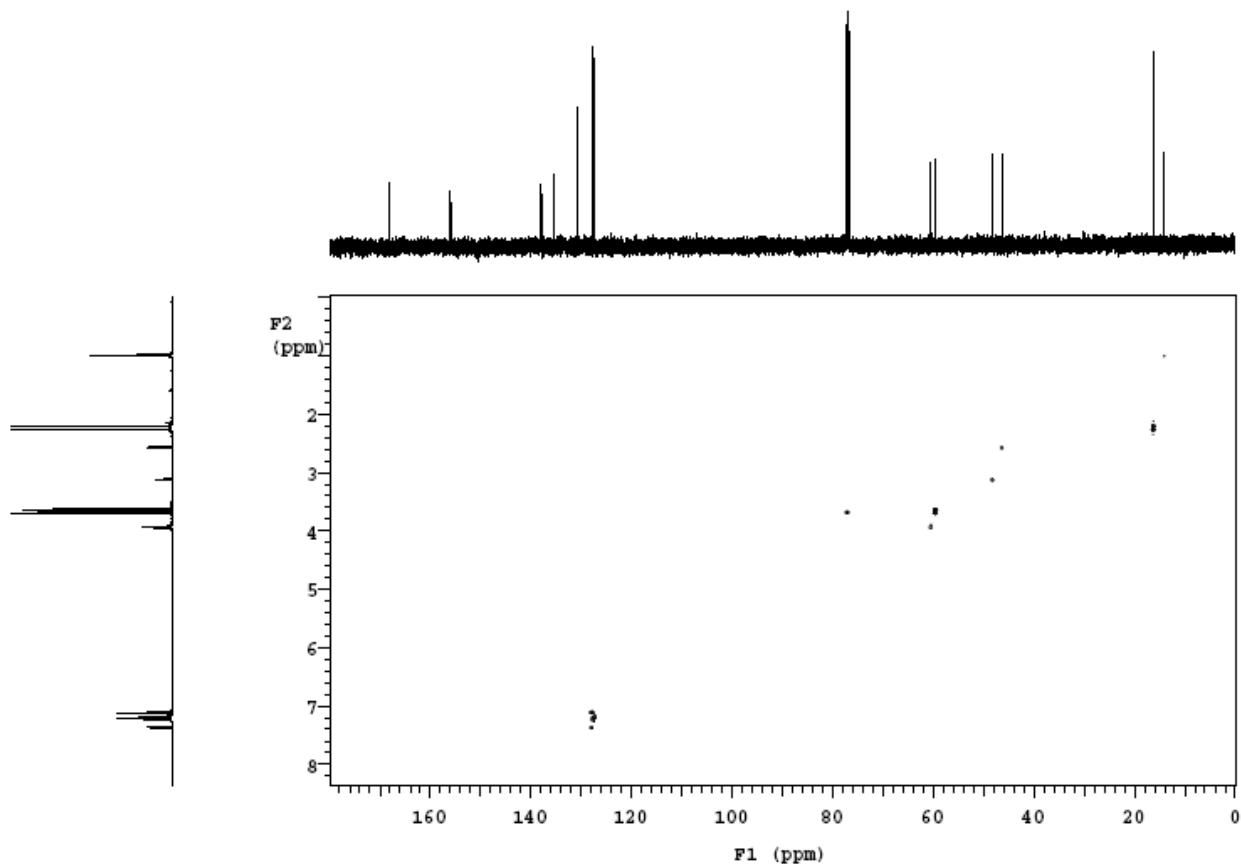

$^1\text{H}$  NMR Spectrum of **4a** from a KIE experiment (500 MHz,  $\text{CDCl}_3$ ):

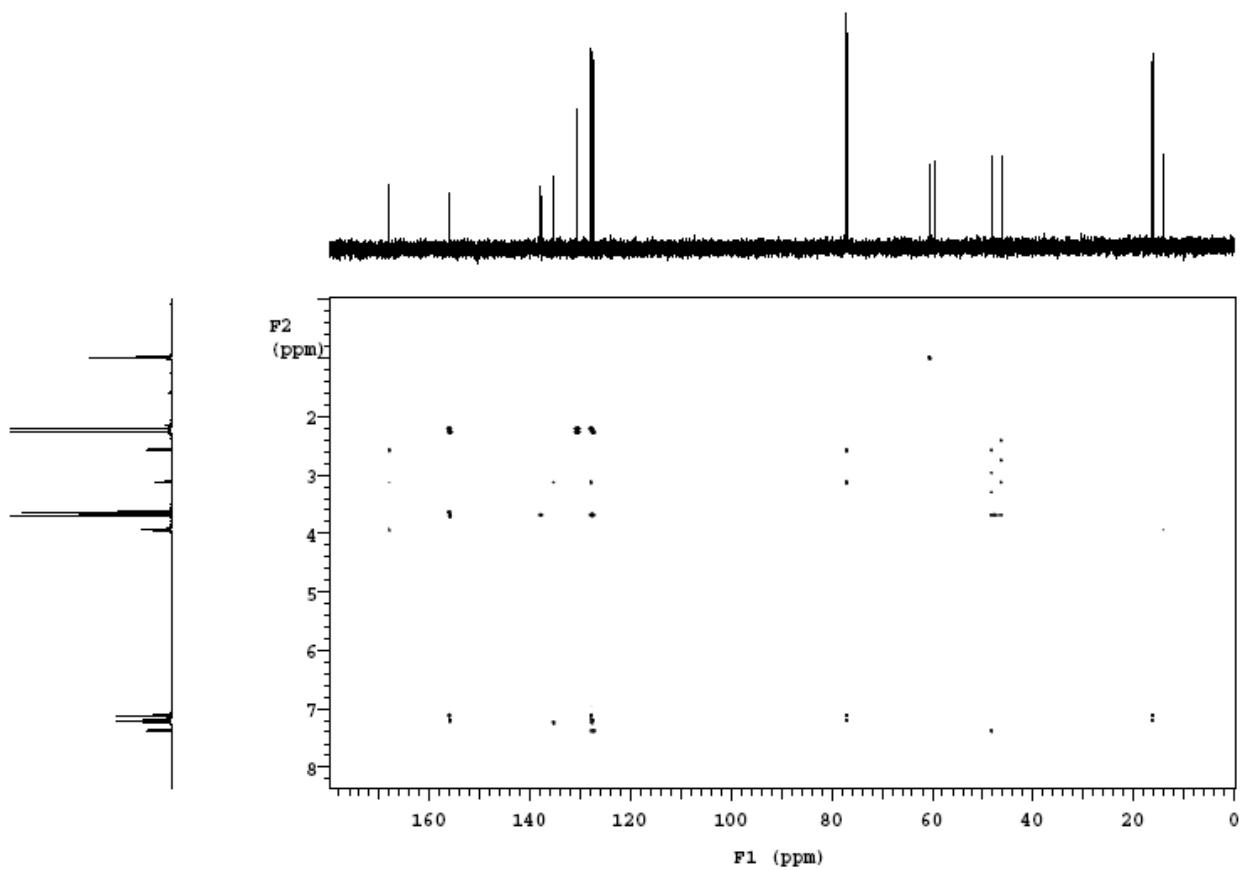

$^{13}\text{C}$  NMR Spectrum of **4a** from a KIE experiment (125 MHz,  $\text{CDCl}_3$ ):

2-D HMQC (Heteronuclear Multiple Quantum Coherence) experiment NMR Spectrum ( $\text{CDCl}_3$ ):

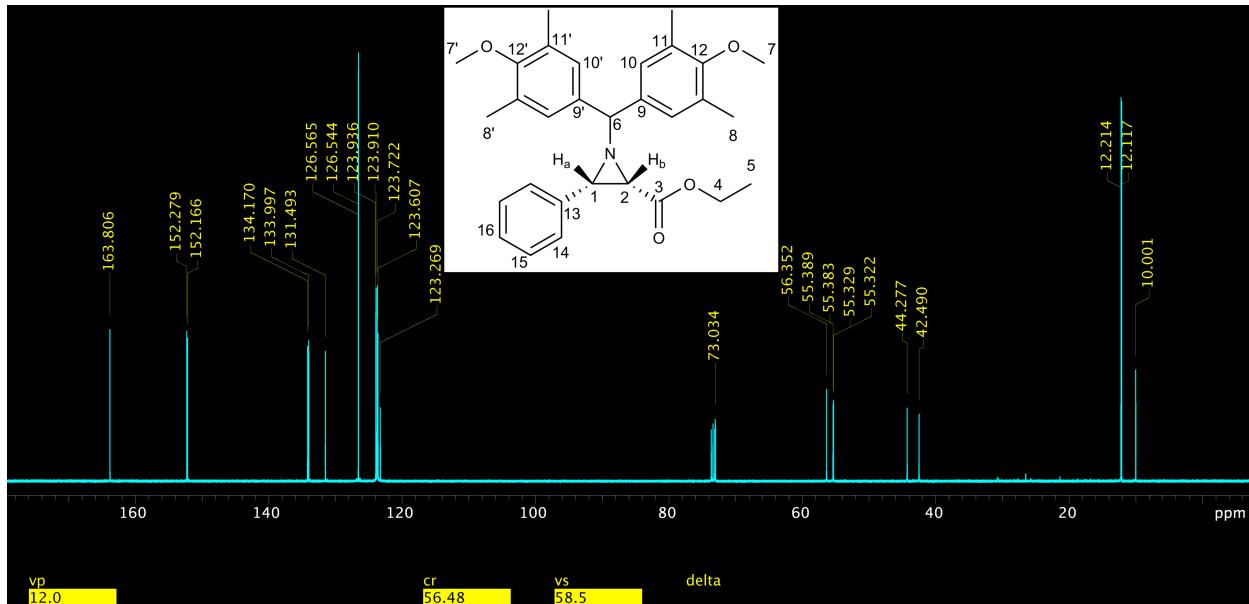

2-D HMBC (Heteronuclear Multiple Bond Correlation) experiment NMR Spectrum ( $\text{CDCl}_3$ ):

## D. NMR measurements and trivial KIEs

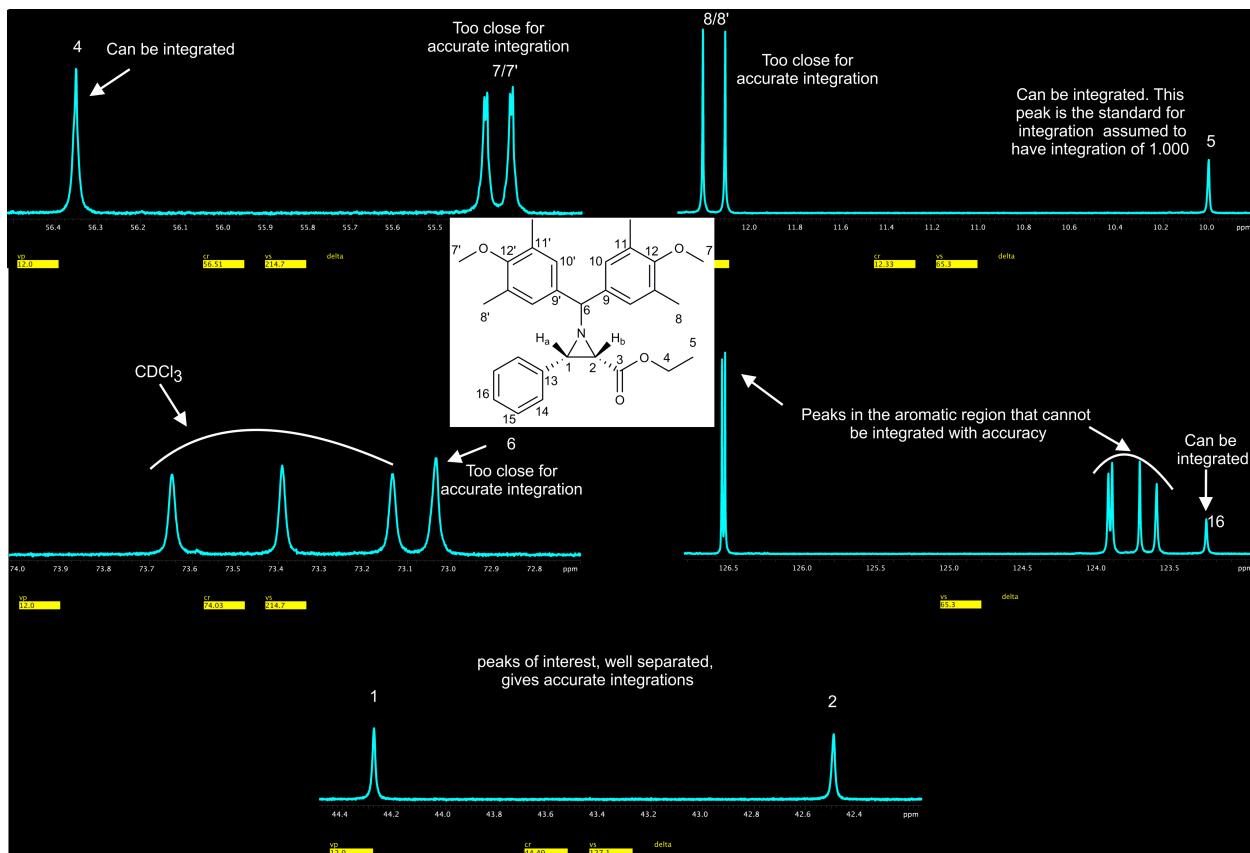

All samples were prepared using a constant 450 mg of **4a** in 5 mm NMR tubes filled with  $\text{CDCl}_3$  to a constant height of 5.5 cm. The  $^{13}\text{C}$  spectra were recorded at 125 MHz using inverse gated decoupling, 15 s (5 times T1) delays between calibrated  $\pi/2$  pulses, and a 5.0 s acquisition time. Integrations were determined numerically using a constant integration region for each peak. A zero-order baseline correction was generally applied, but in no case was a first-order (tilt) correction applied. Six spectra each with 512 transients were obtained for each four samples of **4a** (two samples per experiment). The integration of the methyl peak of the ester moiety of **4a** (peak 5, Figure S2) was set to 1.000 since the KIE at this position is expected to be negligible.

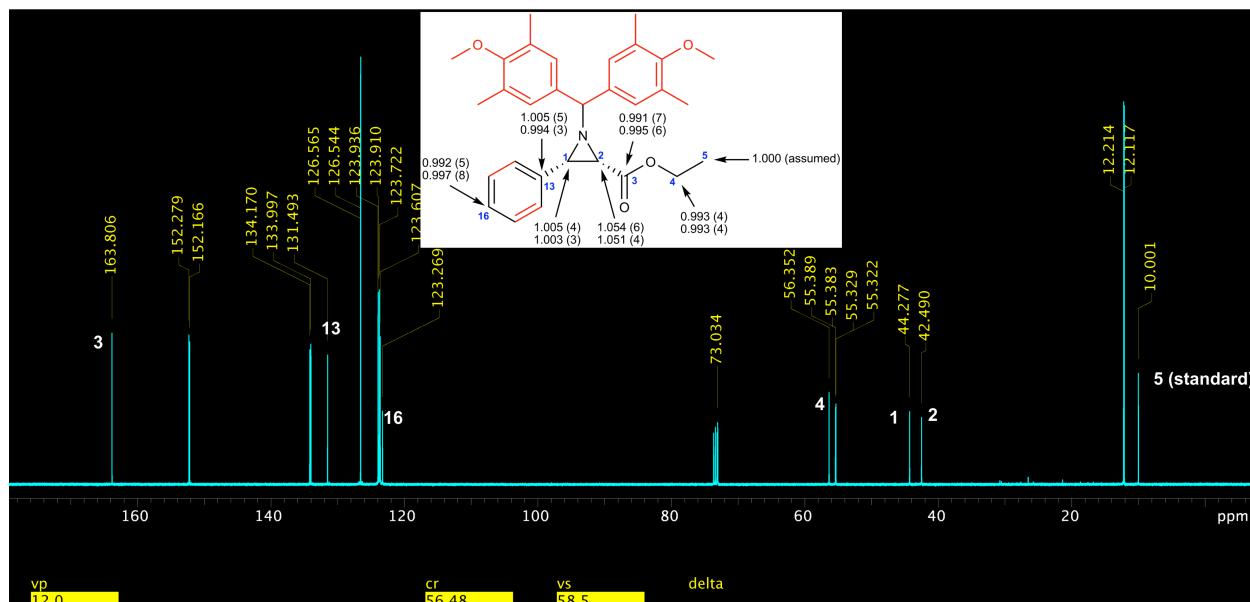

**Figure S2.** Representative NMR spectrum showing accurate chemical shift that illustrates near-overlap of several peaks and the good separation of the peaks of interest.  $\text{CDCl}_3$  is at  $\delta$  73.4.

Using the Singleton method, one can measure the KIE for every carbon in a molecule provided the peaks are well separated. We were fortunate that the peaks of interest in **4a**, namely C1, C2, C5 ( $\delta$  44.277, 42.490 and 10.001, Figure S2) were separated from all other peaks by at least 2 ppm. This enables us to use C5 as the standard peak and accurately determine the integrations of C1 and C2 (see Figure S3). This is one of the largest published molecules used for KIE analysis by the Singleton method. The primary goal during acquisition of NMR spectra for KIE measurements was to have the best line shapes and line widths for the peaks of interest including the standard peak.

Due to the diastereotopic nature of the aromatic groups on the MEDAM moiety, there were several pairs of peaks that were too close for accurate reproducible integrations (Figure S3).

**Figure S3.** Peaks that are easily integrated versus ones that are too close for reproducible integrations.

**Figure S4.** Spectrum highlighting the well-separated peaks and the corresponding KIEs from two experiments. The carbon atoms shown in red are the ones that were too close for meaningful integrations. Nevertheless, the spectrum was acquired with a delay time of 5 times the T1 relaxation time of the peak with the largest T1 relaxation time.

## 2. Theoretical Section

### A. Methods and general comments

The ONIOM calculations were setup using GaussView 5.0 (the interface between Gaussian and Windows). Intermediates were located by performing IRC calculations from the relevant transition structures and optimizing the geometry of the resulting structures. A thorough conformational search was also performed for locating the lowest energy starting materials used for the calculation of theoretical KIEs.

**TS<sub>conf</sub>** was located after a careful conformational search performed by fixing the dihedral angle (between the C2-N<sub>2</sub><sup>+</sup> (diazonium) and the C1-N (imine) bond along the C1-C2 bond) at a series of values between -100° and -130° and locating the energy maxima. A transition state search was then performed on this geometry to arrive at the unrestricted **TS<sub>conf</sub>** with one imaginary frequency of ~ -6, which corresponds to bond rotation about the C1-C2 bond. The KIE for this transition state was computed as an equilibrium isotope effect between **TS<sub>conf</sub>** and free starting material, since imaginary frequencies below -50 cannot be used by ISOEFF98 for the prediction of KIEs. This is expected to make little or no difference to the actual value of the KIEs since there is no bond formation/breaking occurring at this transition state.

A very detailed search was performed for locating the lowest energy carbon-carbon bond forming (**TS1** in main text and **TS1a-d** in Supporting Information) and ring-closing (**TS2** in main text and **TS2a – TS2f** in Supporting Information) transition states. Finally, Single-point energies were performed on TS1, TS2, TS3 and TS4 using M062x/6-31+G\*\* method and a PCM model for toluene (reaction solvent) to further support that the trends in the relative energies of the transition structures reported in the paper. The relative energies of the addition and ring-closing transition structure from these single-point energy calculations for the *cis*- and *trans*- aziridination pathway are shown below.

	Relative Gibbs Free Energies (from Figure 9) (kcal/mol)	Relative Potential Energies (kcal/mol) M062x/6-31+G** (toluene)
<b>TS1</b>	0.0	0.0
<b>TS2</b>	4.0	8.2
<b>TS3</b>	0.0	0.0
<b>TS4</b>	0.6	1.4
