

SUPPLEMENTARY INFORMATION

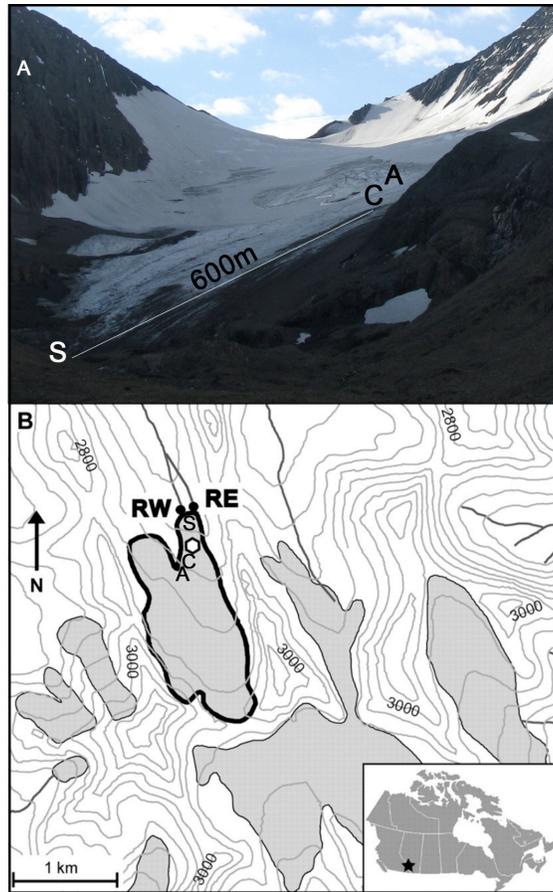

METHODS

Sample Collection. Subglacial sediments were collected aseptically from the eastern drainage of Robertson Glacier (RE) using spatulas and spoons that were flame sterilized immediately before sample collection. Fine-grained sediments were collected from a point ~ 1 meter from the back of an ice cave at RE. RE was selected over the western drainage of Robertson Glacier (RW) for sampling due to the unstable nature of the ice cave present at RW. Subglacial sediments were collected from the top 0.5 cm of the sediment deposition zone and subsamples were immediately placed in pre-sterilized microcentrifuge tubes (DNA-based analyses) or microcentrifuge tubes containing 500 μ L RNALater (RNA-based analyses), as described in the main body of the text. Triplicate subsamples of subglacial sediments for use in DNA and RNA-based analyses were collected randomly from 6 sites in the ice cave sediment deposition zone over an area ~ 0.5 m², and then a random draw of 3 aliquots of sediment from 3 of these locations were used in nucleic acid extractions. Cryoconite debris was collected from a prominent (~ 10 cm diameter) cryoconite melt hole ~ 600 m up the glacier from RE. While numerous cryoconite melt holes exist on the surface of RG, this particular melt hole was selected on the basis of its larger size relative to other adjacent melt holes and the hypothesis that surface discharge from this collection of melt holes would potentially drain into the subglacial environment via the largest moulin on the surface of the glacier. Triplicate ~ 1 g subsamples of sediment were collected randomly from the top 0.5 cm of the sediment layer for use in DNA- and RNA-based analyses, as described above. The site for collecting snow from the surface of RG was also chosen on the basis of its close proximity to the very large moulin on the surface of

RG and the hypothesis that debris from the melt water would feed into the subglacial environment through this feature. The surface layer (down to ~1 cm depth) of the snow was loosely packed into 3 sterile 500-mL sterile polypropylene bottles using a flame-sterilized spoon. The triplicate subsamples of snow were sampled over an area of ~ 4 m². All subglacial sediment, cryoconite, and snow samples were frozen immediately using dry ice. Samples were transported from the field site to Montana State University on dry ice and, once at the lab, were placed at -80°C until further processed. At the lab snow samples were thawed at 4°C, homogenized by shaking, and dispensed into clean and autoclave-sterilized 500-mL centrifuge bottles. The debris in the melted snow was concentrated via centrifugation (14,000 x g, 5 min., 4°C). Following centrifugation, melt water was decanted and the debris pellet from each triplicate sample was transferred into triplicate bead beating tubes using a sterilized spatula and subjected to nucleic acid extraction immediately. The dry weight solids content of the snow debris, subglacial sediments and cryoconite sediments was determined by drying the material left after bead beating extraction at 80°C for 24 hrs.

The temperature and pH of the fluids overlaying the subglacial sediments and cryoconite debris were determined using a temperature compensated model 59002-00 Cole-Parmer electrode. An alcohol thermometer was used to confirm temperature. The temperature of snow was measured by inserting the alcohol thermometer laterally in the top 0.5 cm of the snow. The pH of the snow was determined using the decanted melt water. The conductivity of the fluids overlaying the subglacial sediments and cryoconite debris was determined using a YSI model 33 S-C-T meter (Yellow Springs Instrument Company, Inc., Yellow Springs, Ohio). Conductivity

values were standardized to a common temperature of 25.0°C as previously described (Hamilton et al, 2011). Additional details of the chemistry of the fluids overlaying subglacial sediments as well as subglacial sediment porewater chemistry has been previously reported (Boyd et al, 2010, Boyd et al, 2011).

Supp. Fig. 1. Photograph from the terminus of Robertson Glacier looking up the glacier. Sampling sites are denoted as S: Subglacial sediments; C: Cryoconite melthole; A: snow (Panel A). Topographic map of Robertson Glacier showing the RE and RW subglacial stream drainages and the location of the sampling sites, S: Subglacial sediments; C: Cryoconite melthole; A: snow. The location of RG (star) in Alberta, Canada is shown in the inset (Panel B). Map adapted from Boyd et al, 2011.

Supplemental Table 1. Physical and chemical data for the subglacial meltwater at the site of subglacial sediment collection. Measurements were also performed on the water overlaying the cryoconite melt hole and on melted snow.

Sample	pH	Temp. (°C)	Cond. (µmhos/cm)
Subglacial	8.8	0.3	110
Cryoconite	8.2	0.1	18
Snow ^a	7.0	0.1	-

^apH measured after melting, conductivity not measured.
