Sequences of OTUs present at >1% relative abundance

The following 16S rRNA amplicon sequences correspond to the OTUs shown in Figs. 5&6. They have been processed as described in the materials and methods. The header line for each sequence contains the greengenes taxonomy followed by white space and then a short name used in the manuscript. The raw sequence data can be downloaded from the Short Read Archive SRP021172.

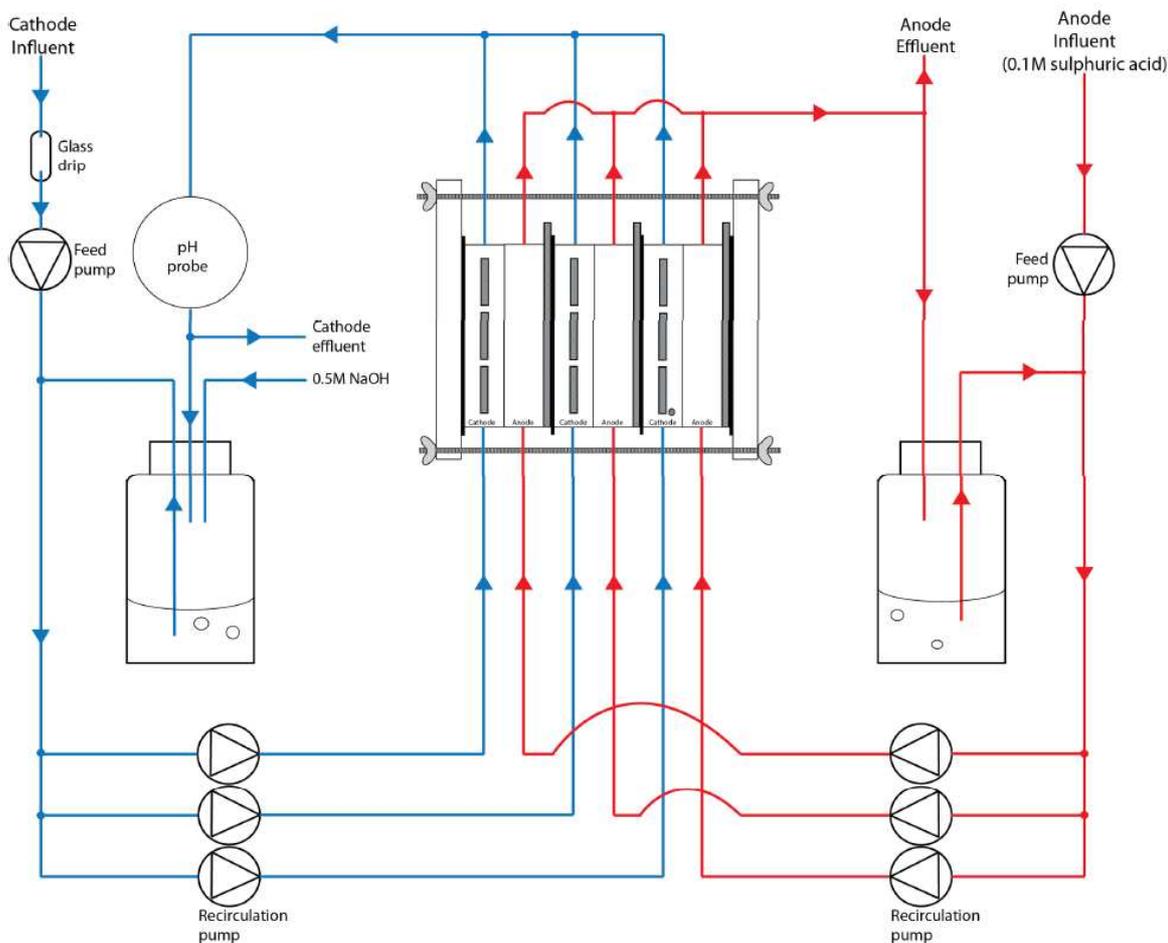

Fig. S1 Schematic diagram of the recirculation and feed circuits. Cathode flow is indicated in blue, anode flow in red. Cathode influent was pumped into the cathodic electrolyte recirculation stream at 3 L day^{-1} through a glass drip to avoid contamination of the stock solution. The influent was split into three pump channels before entering each cathode at a flow rate of 80 mL min^{-1} . The cathode was maintained at pH 5.5 by automated NaOH dosing. The anode influent (0.1 M sulphuric acid) was pumped into the anode electrolyte recirculation stream at 3 L day^{-1} . The anode electrolyte was also split into three pump channels before entering each anode at a flow rate of 80 mL min^{-1} . Excess electrolytes were drained from both cathodes and anodes from overflow tubes.

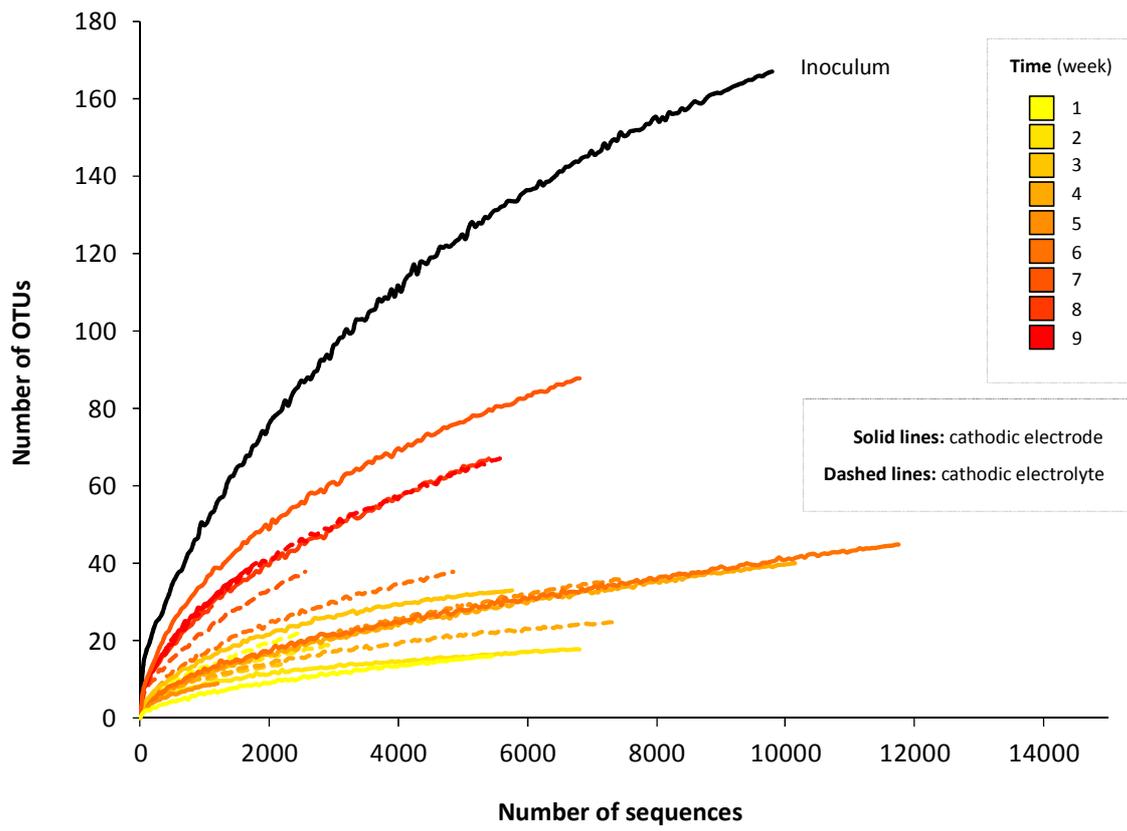

Fig. S2 Individual-based rarefaction curves for each sample.

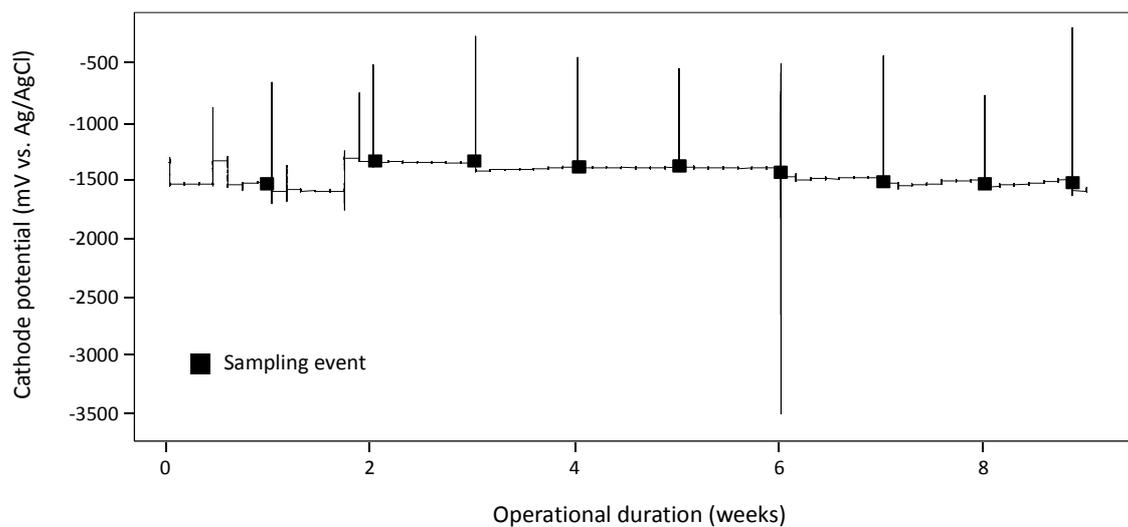

Fig. S3 Cathode potential over time during galvanostatic operation at -0.32 mA cm^{-2} . The spikes occur when the potentiostat/galvanostat is paused for sampling.
