Supplementary References

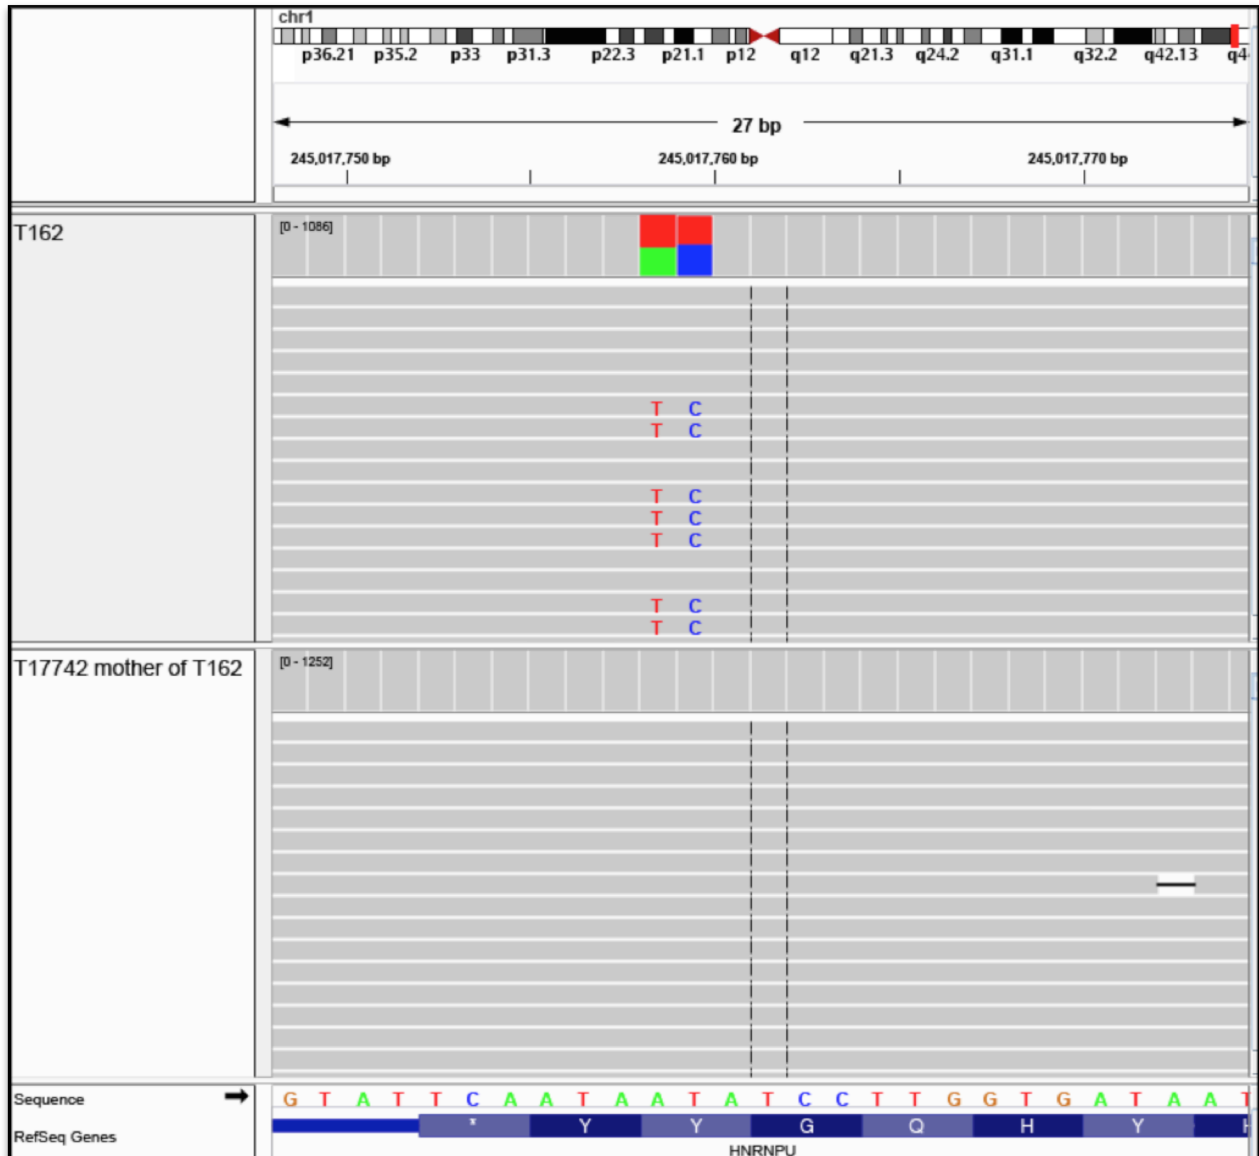

Supplementary Figure 1 Targeted resequencing strategy carried out in 500 patients with epileptic encephalopathy. Disease gene identification was conducted under a *de novo*/dominant inheritance model, except for #recessive, &X-linked recessive, ^X-linked but female restricted and *disruption of maternally expressed (paternally imprinted) genes. Genes in which we identified pathogenic variants appear in bold.

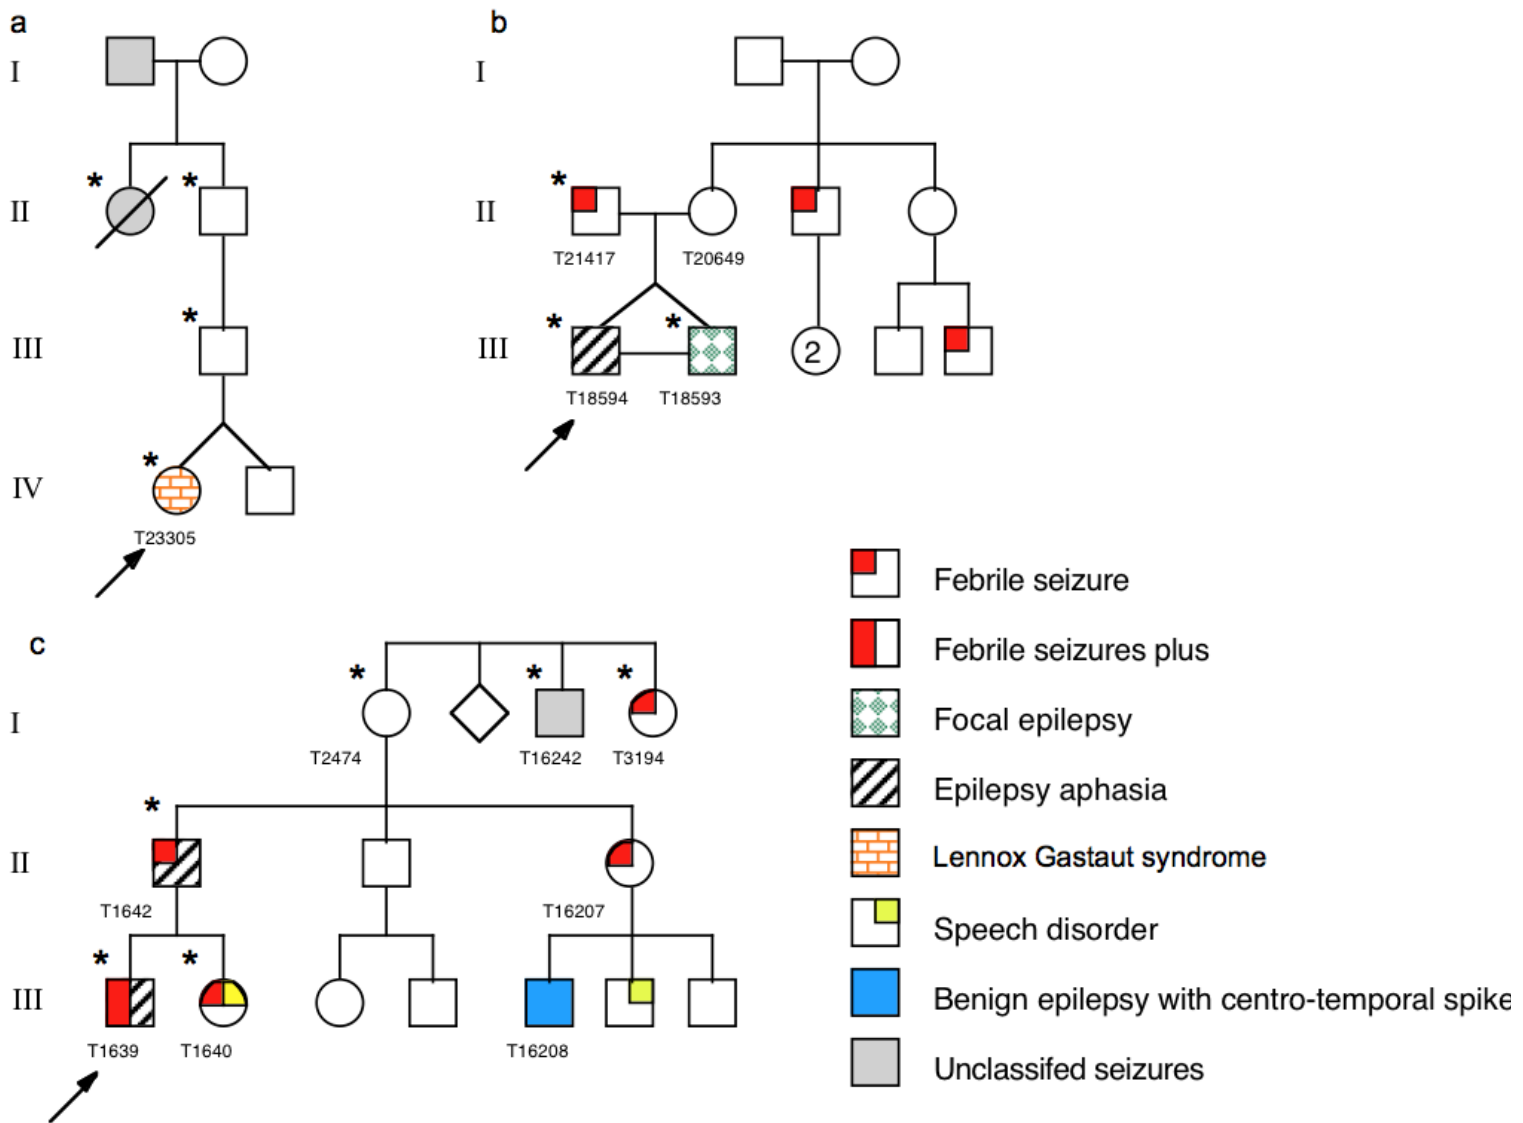

Supplementary Figure 2 Percentage of target gene resequenced at >25X for a) CNV candidate genes b) epilepsy-associated genes and c) known epileptic encephalopathy genes. GATK Depth of Coverage tool was used to calculate the percentage of exonic bases (and 5bp flanking) covered at >25X in each sample for each gene. The average coverage across all samples is reported.

Supplementary Figure 3 Microdeletions of the 15q26.1 region encompassing *CHD2*. The *CHD2* gene and a uncharacterized non-coding RNA (LOC100507217) were the only two genes common to the two previously reported 15q26del in probands with EE^{1,2}, as well as the unpublished deletion we identified in a proband (T2948) with photosensitive generalized early-onset epilepsy and ID. *CHD2* was selected as a candidate gene for mutation screening in our cohort of 500 epileptic encephalopathy probands.

Supplementary Figure 4 The p.Y805X *HNRNPU* variant in proband T162. Output from the Integrated Genome Viewer (IGV) shows the c.471T>C and c.472A>T in the proband, T162 (top panel). Neither variant was present in the proband's mother T17742 (bottom panel).

Supplementary Figure 5 Pedigrees of segregating variants in known EE genes. a) The pedigree showing the *PCDH19* Arg911Gln mutation resulting in the LGS phenotype in the proband and developmental delay and seizures in her paternal great-aunt. Carrier males exhibit no phenotype, as expected for *PCDH19* mutations that cause epilepsy phenotypes in females only. b) The *SCN1A* Asp454Asn variant present in affected monozygotic twins as well as their father with febrile seizures. c) The Arg1988Trp *SCN1A* change in a proband with epilepsy aphasia and febrile seizures plus; the variant segregates with various types of epilepsy with variable expressivity and incomplete penetrance.

Supplementary Table 1 Potentially disruptive variants in known epileptic encephalopathy genes.

father or * neither parent available for segregation analysis

Supplementary Note: Candidate gene selection from epilepsy-associated CNVs

We considered all genes encompassed by 138 unique epilepsy-associated CNVs either from published cohorts, case reports or unpublished data²⁻⁴. These CNVs encompassed 1309 genes, we selected only those that were expressed in the brain (n=705). These 705 'candidate genes' were prioritized based on a number of criteria. Firstly, we compared overlapping CNVs, and defined a critical interval. For a small number of genomic regions, only one or two genes were encompassed by the overlapping intervals, and these were prioritized (n=4) (Sup Table 2) . Over larger genomic intervals that were not amenable to mapping, we performed a thorough literature search of genes in the region and applied bioinformatics tools for candidate gene prioritization, using the bioinformatics tools, ToppGene Suite⁵, Endeavour⁶, String⁷ and the Ingenuity Pathway Analysis software (IPA) (see URLs). The ToppGene and Endeavour tools were used to rank candidate genes based on similarity to a training set of known epilepsy genes (n=115, see list below) using default settings. The ToppNet tool, was used to rank candidate genes based on relationships to a protein-protein interaction networks, also generated from the training set of genes. String was used to generate protein-protein interaction networks between the candidate and training set genes, using a high confidence threshold (0.700). Similarly, pathway analysis was conducted using IPA, with both sets of genes. Candidate genes that were consistently ranked as 'high priority' by ranking tools and/or those that were enriched within protein-protein interaction networks and canonical pathways were prioritized. Furthermore, we performed an intersection between candidate genes and those within the Mouse Genome Informatics (MGI) database that were known to generate phenotypes affecting the 'nervous system'. Finally, genes with a high burden of truncating variants in the ESP6500 (see URLs) control dataset were not selected. Using this tiered prioritization strategy, a total of 18 genes were selected for targeted resequencing. We also selected five genes that were members of the same gene family as a CNV candidate gene (homology to CNV candidate). Finally, literature searches resulted in the inclusion of six additional genes that were hypothesized as candidate genes based on function and/or animal models (literature candidate).

*SMARCA2 mutations have since been shown to cause Nicolaides Baraitser syndrome¹⁵, SMARCA2 was selected as a CNV candidate gene prior to this publication. Similarly mutations in AKT3 have been shown to cause hemimegalencephaly¹⁶.
