

Integrative transcriptome analysis reveals dysregulation of canonical cancer molecular pathways in placenta leading to preeclampsia

Figure S1. Study Design Flow Chart

Our integrative analysis involved interrogating a preeclampsia-specific gene list obtained from meta-analysis of case-control studies in several relevant data sources, which included expression arrays of normal and time-course placentas (i.e., placenta from first, second and third trimester pregnancies), hypoxic trophoblasts, and *XPD*^{TTD} fibroblasts (i.e., cells predisposed to preeclampsia). These data sources were specifically chosen in order to filter the differentially-expressed genes and pathways to select those which preceded the development of the clinical symptoms of preeclampsia.

Figure S2. Protein-level expression of selected preeclampsia genes in normal placenta

Protein level expression analysis of selected genes found to be differentially-expressed in preeclamptic placentas from meta-analysis of preeclampsia case-control studies, using a protein atlas database (proteinatlas.org). Selected genes included secreted factors (FLT1, LEP, CRH, GH1), membrane-bound molecules (ENG, ADAM12, EGFR), nuclear (ATF3) and stromal (FBN2) proteins. Localization of all examined proteins was noted in trophoblasts except for FBN2, which was found expressed in extracellular matrix.

Figure S3. Comparison of preeclampsia gene signature with that of cells treated with shATF3.

Panel a. Venn diagram showing shared genes between preeclampsia and ATF3 deficient cells (shATF3).

Panel b. Heatmap showing fold changes in the respective datasets of common genes identified in **Panel**

a. Red arrows show that FLT1, ENG and INHBA are downregulated after treatment of K562 cells with

shATF3. **Panel c.** Visualization of ATF3 binding to promoter region (approximately 1kb from transcription

start site of Flt1 gene) in mouse dendritic cells(GSM881126³¹).
