“The GlycoFilter: A Simple and Comprehensive Sample Preparation Platform for N-glycome and N-glycoproteome”

Hui Zhou, John W. Froehlich, Andrew C. Briscoe, Richard S. Lee

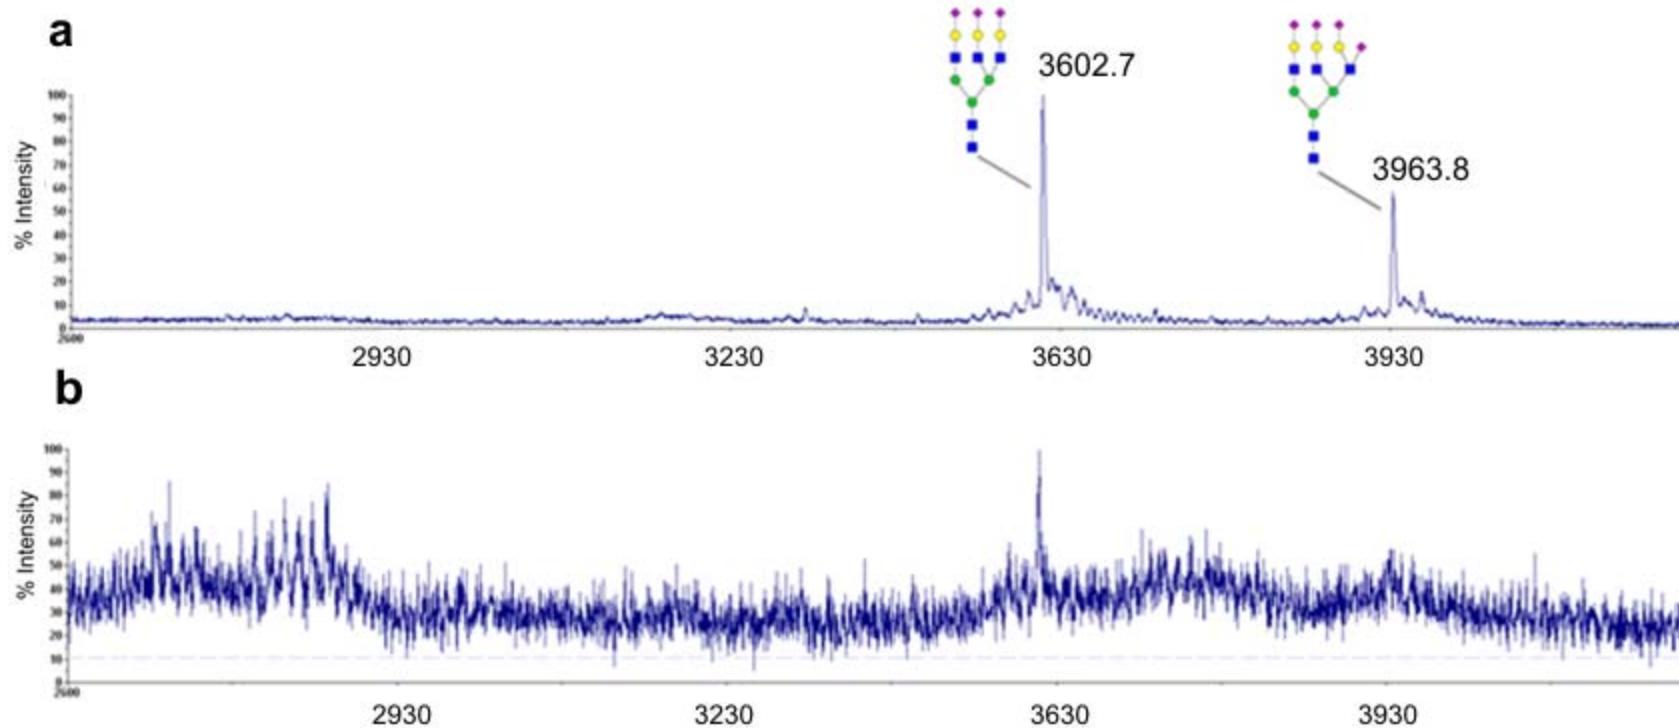

Supplementary Figure S1	MALDI-MS of N-glycans of RNase B (a) 1 ug, (b) 5 ug, and (c) 10 ug
Supplementary Figure S2	MALDI-MS of Fetusin N-glycans (without acidification vs. acidification)
Supplementary Figure S3	ESI-MS and MS/MS spectra of two minor N-glycans from bovine fetuin
Supplementary Figure S4	MALDI-MS of N-glycans of serum IgG
Supplementary Figure S5	MALDI-MS of permethylated urinary N-glycans by extended acidic elutions and the remaining N-glycans in the protein solution
Supplementary Figure S6	Experimental workflow to determine the impact of PNGase F catalyzed de-N-glycosylation on urinary proteomic performance
Supplementary Figure S7	MALDI-MS of N-glycans of three human plasma samples
Supplementary Table S1	The list of N-glycan monosaccharide composition of U1
Supplementary Table S2	The list of N-glycan monosaccharide composition of U2
Supplementary Table S3	The list of N-glycan monosaccharide composition of U3
Supplementary Table S4	The summary of proteins identified in both preparations +PNGase F and Control
Supplementary Table S5	The list of identified glycosites from three urine samples

Supplementary Table S6 The summary of proteome and glycoproteome of three human plasma samples

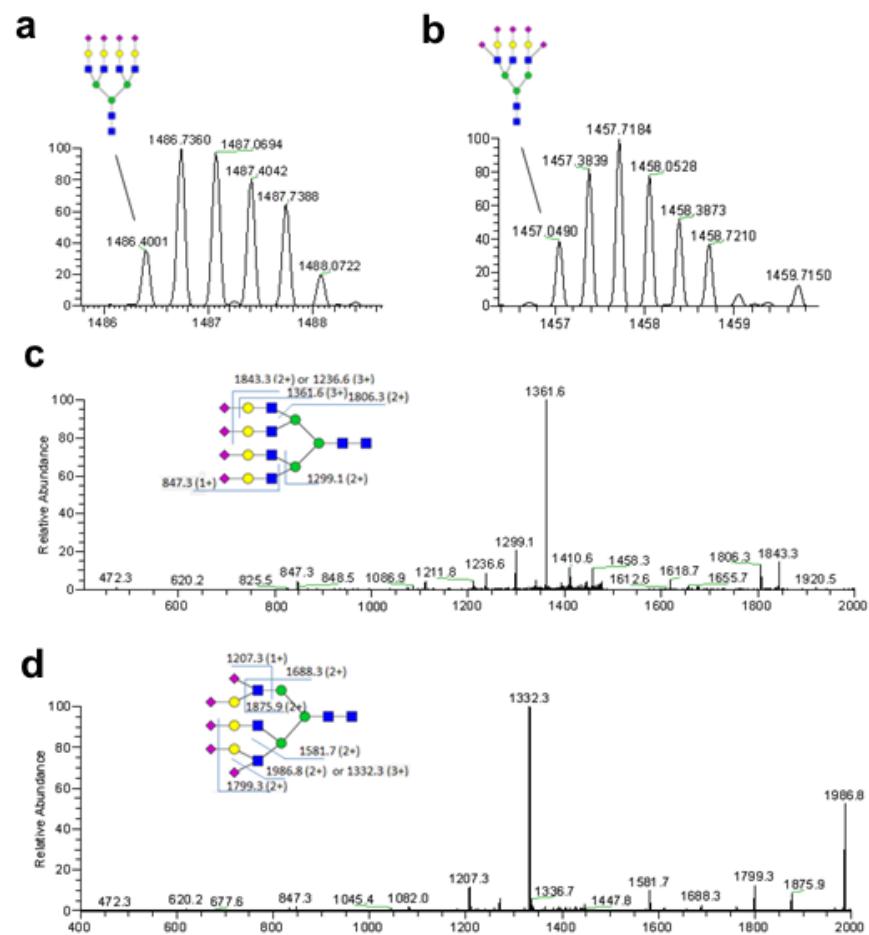

Supplementary Table S7 The list of identified glycosites from three plasma samples

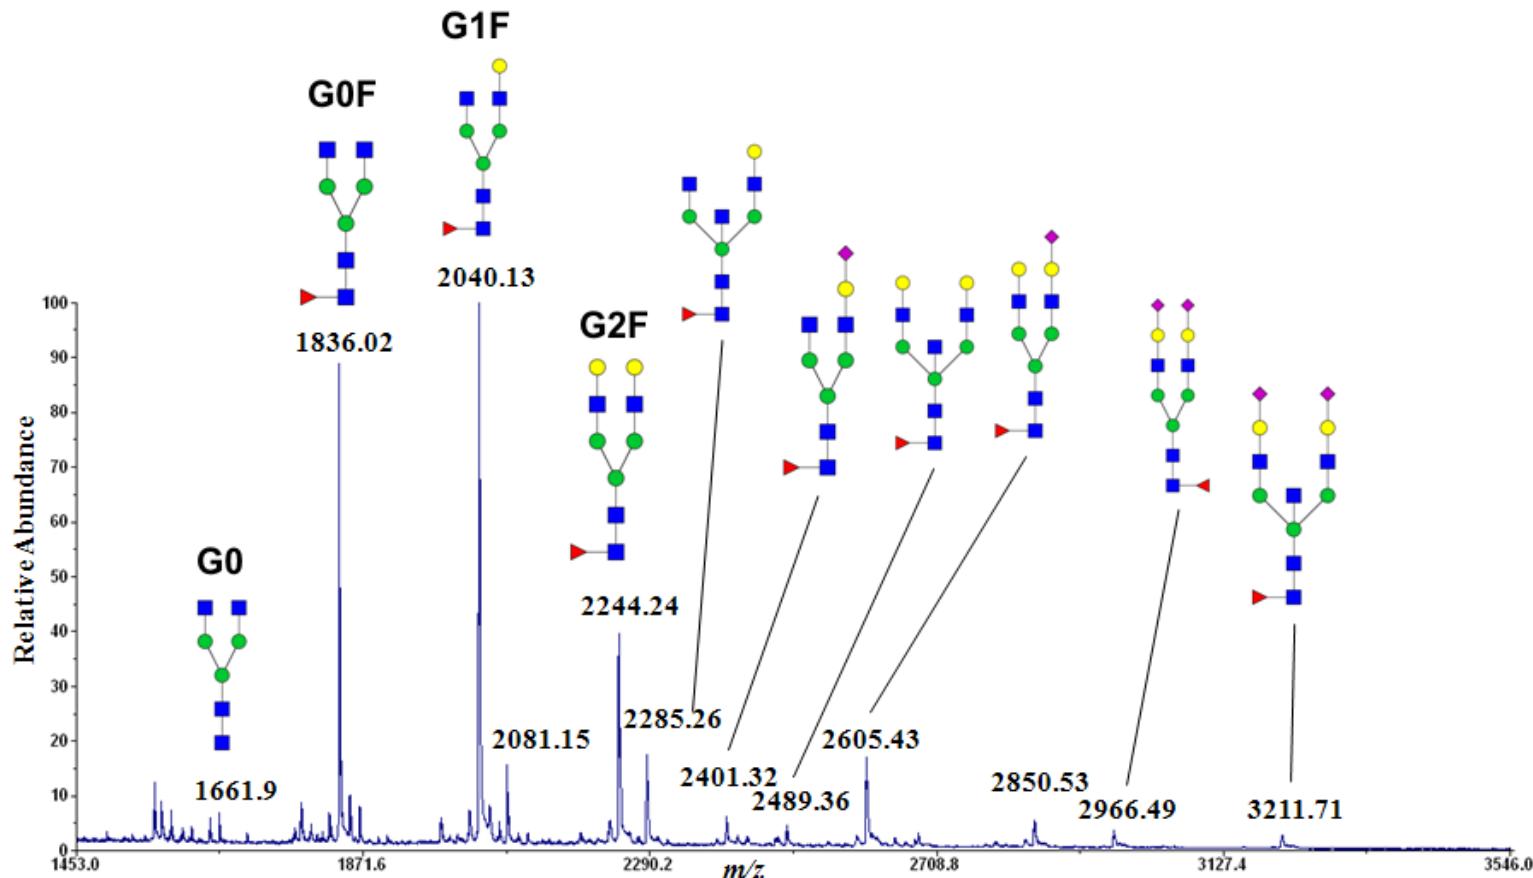

Supplementary Figure S1 | The MALDI-MS of permethylated N-glycans from bovine RNase B at **a)** 1 μ g, **b)** 5 μ g, and **c)** 10 μ g, which were collected separately using the GlycoFilter platform. All known high-mannose type N-glycans (**Man 5**, **Man 6**, **Man7**, **Man 8**, and **Man 9**) were detected in all samples with the same peak intensity pattern as previously reported(1). All ions were single sodium adducts $[M+Na]^+$ and the monoisotopic peak was annotated.

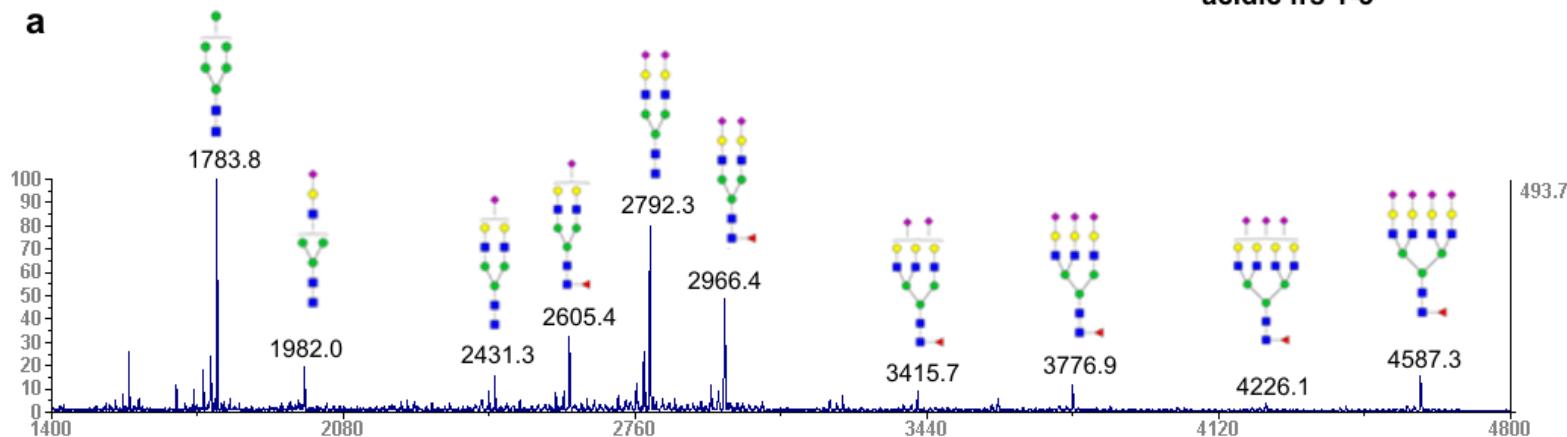

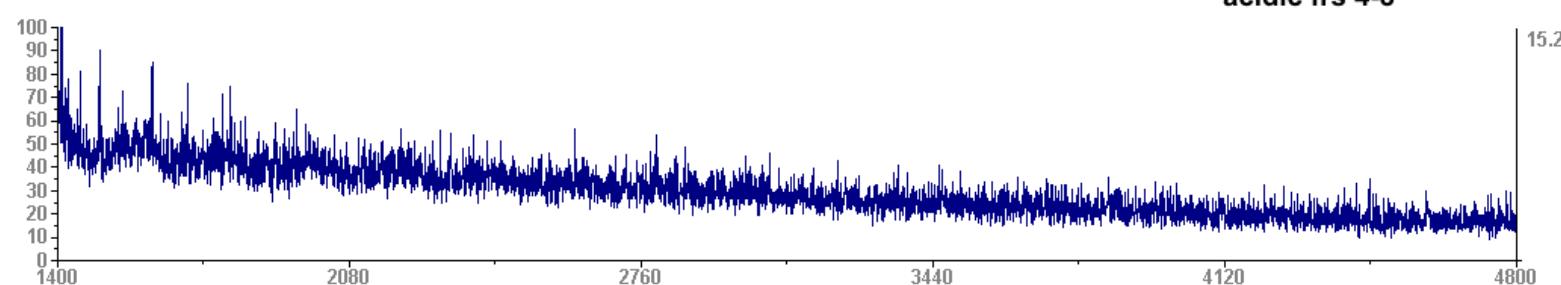

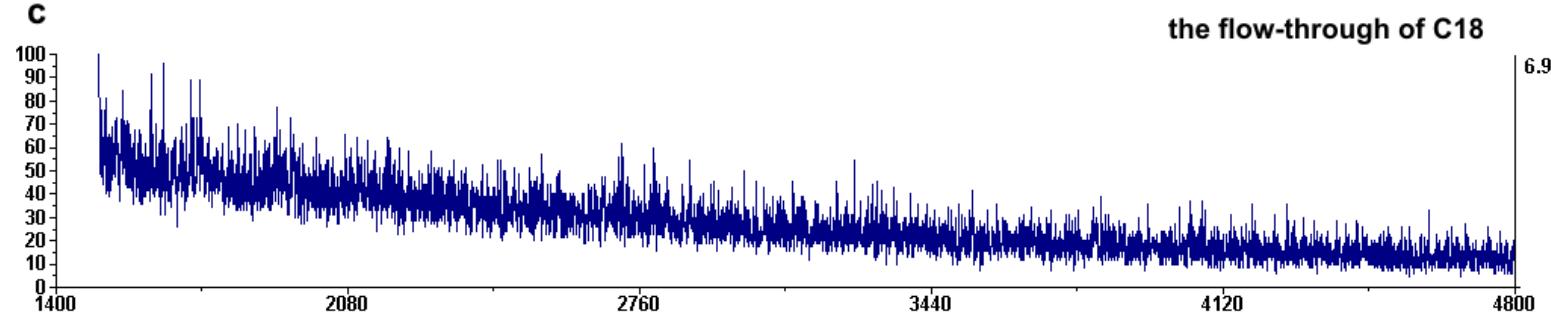

Supplementary Figure S2 | The MALDI-MS of permethylated N-glycans of bovine fetuin. **(a)** The remaining N-glycans in the sample chamber of the filter device without acidification; and **(b)** the remaining N-glycans in the sample chamber of the filter device after acidification. Highly sialic acidic N-glycans were selectively retained in the sample chamber **(a)** due to the ionic interactions between the glycans and protein at neutral or basic conditions. After acidifying, these interactions were effectively interrupted, allowing the elution of large glycans with multiple sialic acid residues by filtration **(b)**. All ions were single sodium adducts $[M+Na]^+$ and the monoisotopic peak was annotated.

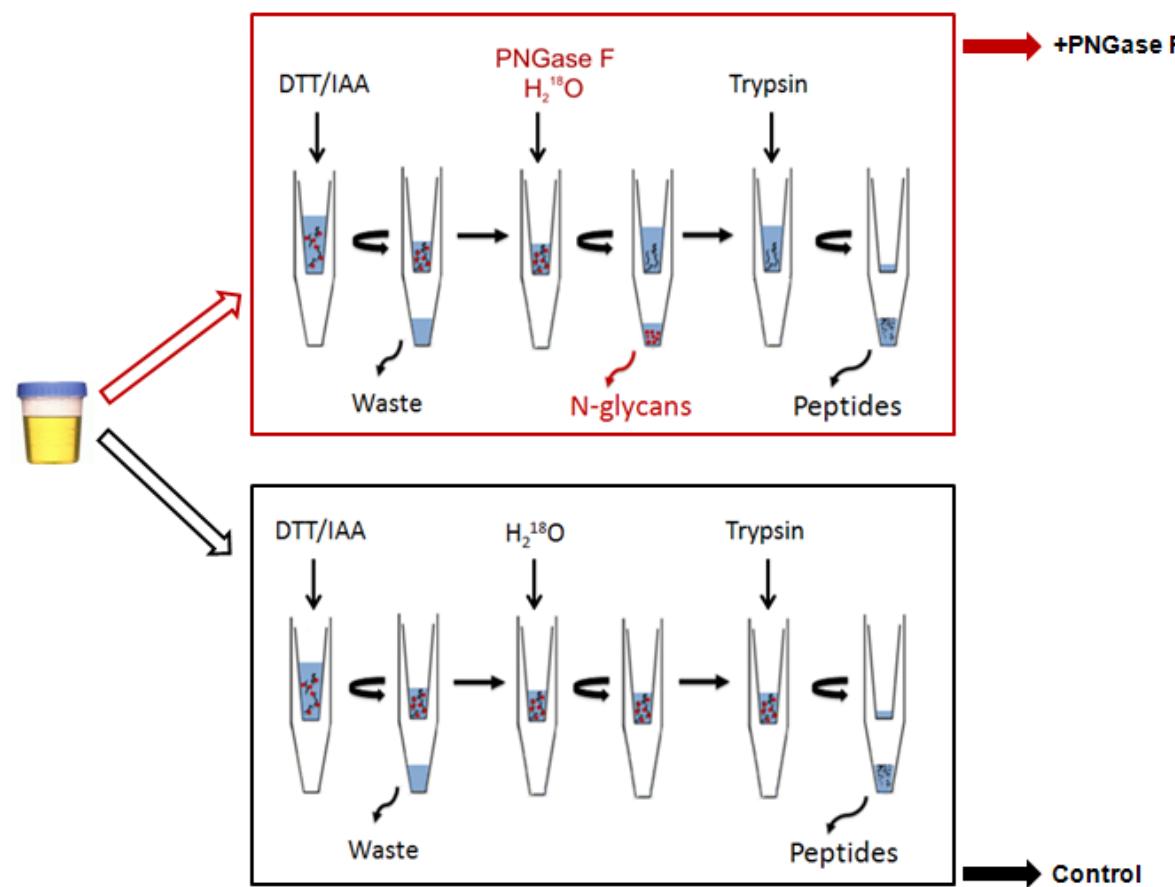

Supplementary Figure S3 | High mass accuracy ESI-MS and CID MS/MS spectra of two unreported N-glycans released from bovine fetuin: m/z 1486.4001 (3+, $\Delta = 8$ ppm), Hex₇HexNAc₆Neu5Ac₄ (**a**, **c**); and m/z 1457.0490 (3+, $\Delta = 8$ ppm), Hex₆HexNAc₅Neu5Ac₅ (**b**, **d**). The charge state of the fragment ions are annotated in parenthesis. All ions were sodium adducts and the monoisotopic peak was annotated.

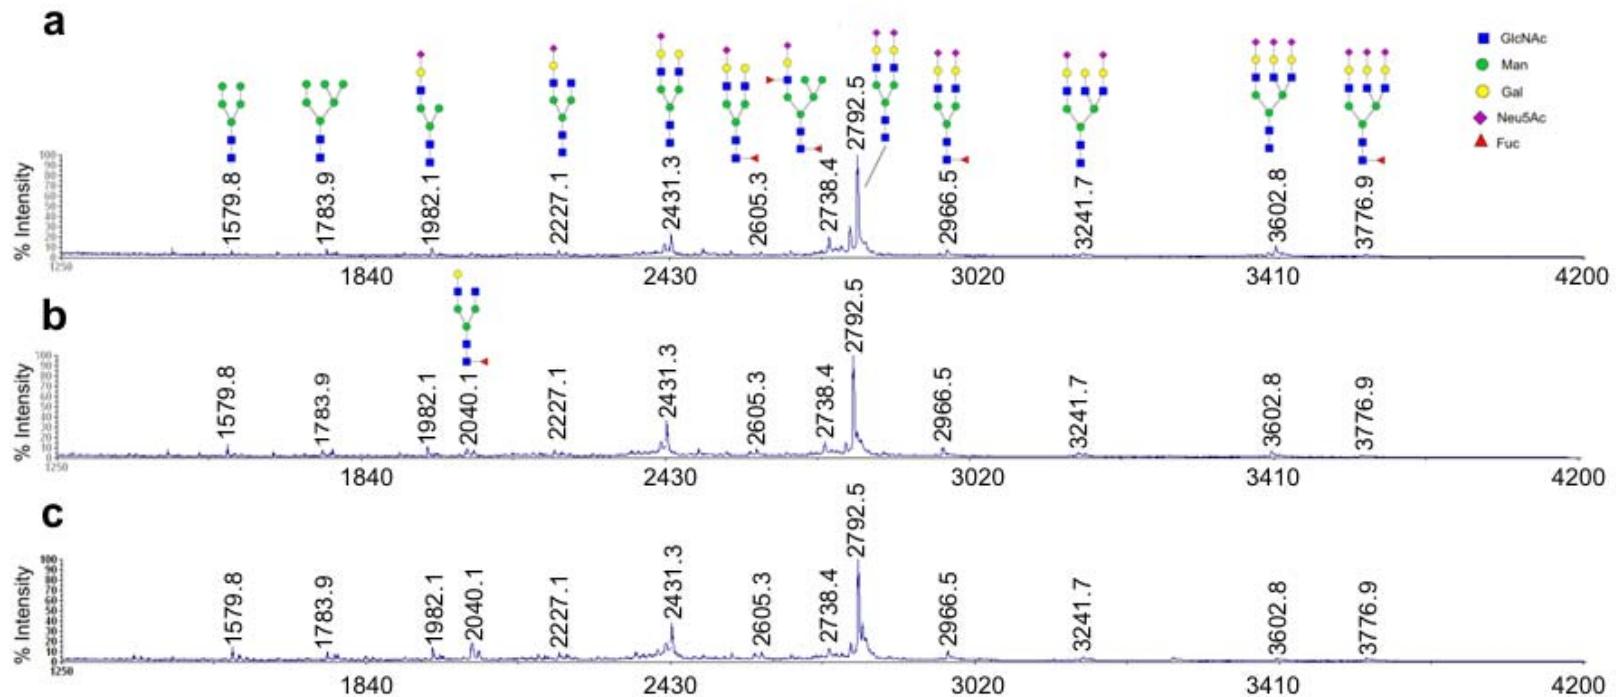

Supplementary Figure S4 | The MALDI-MS of permethylated N-glycans from serum IgG. As expected, three IgG-type N-glycans, G0F, G1F, and G2F, are the most abundant peaks, and the overall intensity pattern and other minor components were the same as other reports (2). All ions were single sodium adducts $[M+Na]^+$ and the monoisotopic peak was annotated.

acidic frs 1-3**acidic frs 4-8****the flow-through of C18**

Supplementary Figure S5 | An additional urine sample was obtained from the donor of **U1**, and processed by the GlycoFilter platform. The N-glycans were eluted by additional acidic washes (X8) to determine if there were residual glycans not captured. The initial three elutions and the remaining five elutions were respectively combined. Furthermore, the deglycosylated proteins were recovered from the sample chamber of the filter and passed through a C18 SPE cartridge to determine if there were residual glycans with the protein sample. The MALDI-MS of permethylated urinary N-glycans were depicted: **(a)** the combined first three acidic elutions; **(b)** the remaining five acidic elutions; and **(c)** the remaining N-glycans from the protein solution. It clearly demonstrates that three acidic elutions effectively separate the vast majority of urinary N-glycans (including the complex and large acidic glycans) from the proteins by filtration **(a)**. N-glycans were not detected in the additional acidic elutions **(b)**, or in the remaining protein sample processed by C18 SPE **(c)**. All ions were single sodium adducts $[M+Na]^+$ and the monoisotopic peak was annotated.

Supplementary Figure S6 | To evaluate the impact of PNGase F on general proteomic performance, three biological urine samples were each divided into two equivalent aliquots. One aliquot was processed with the addition of PNGase F (**+PNGase F**). The other aliquot was processed in parallel except that there was no addition of PNGase F (**Control**). The peptides obtained from both aliquots were similarly analyzed by LC-MS/MS to assess the impact of PNGase F on proteomic performance. (DTT: dithiothreitol; IAA: iodoacetamide)

Supplementary Figure S7 | MALDI-MS of permethylated N-glycans of three biological plasma samples **(a)** Plasma 1, **(b)** Plasma 2, and **(c)** Plasma 3 separately collected by the GlycoFilter platform. All ions were single sodium adducts $[M+Na]^+$ and the monoisotopic peak was annotated.

Supplementary Table S1 | The monosaccharide compositions of permethylated N-glycans from sample **U1**. The glycans were detected by high mass accuracy ESI-MS. The possible N-glycan composition was determined using the online GlycoMod tool (<http://web.expasy.org/glycomod/>) with the following parameter limits: 1) all returned compositions were assumed to have a core structure of $\text{Man}_3\text{GlcNAc}_2$, 2) all ions existed as sodium adducts, and 3) the mass error is less than 10 ppm to the theoretical calculation of proposed composition(3). No further verifications were conducted. The number in the parenthesis annotates the charge state of ions. **H** (Hex): hexose; **N** (HexNAc): N-acetyl hexosamine; **F** (Fuc): fucose; **A** (Neu5Ac): N-acetylneuraminic acid.

Supplementary Table S4 | A summary of the urinary proteins co-identified in both **+PNGase F** and **Control** aliquots (**Supplementary Fig. S6**). The urinary proteins were divided into two distinct groups, glycoproteins and other proteins. Glycoproteins were defined as proteins being identified by at least one deglycopeptide from **+PNGase F** aliquots. Other proteins were defined as protein identified without any deglycopeptides. The unique peptide count for every co-identified protein was calculated and averaged into two groups: glycoproteins and other proteins. Approximately 2 or more additional unique peptides per protein were identified for the glycoproteins due to the effect of upfront de-N-glycosylation. There was no increase in unique peptides for other proteins after de-N-glycosylation.

Urine Sample	Co-identified proteins	Co-identified proteins		Ave. unique peptide count (+ PNGase F vs. Control)	
		Glycoproteins	Other proteins	Glycoproteins	Other proteins
U1	846	250	596	12.7 vs. 10.2	5.6 vs. 5.3
U2	880	272	608	11.0 vs. 9.5	5.4 vs. 5.6
U3	966	310	656	11.6 vs. 9.8	5.6 vs. 5.6
Total	2692	832	1860	11.7 vs. 9.8	5.5 vs. 5.5

Supplementary Table S5 | The complete list of non-redundant N-glycosites (865), spanning in 458 glycoproteins, identified in three urine samples (**U1**, **U2** and **U3**). G: the site was detected as the deglycosylated form only (¹⁸O-incorporated aspartic acid); N: the glycosite was detected as the non-glycosylated form only (asparagine); P: the glycosite was detected as both the non-glycosylated and deglycosylated forms; (-): the glycosite was not detected. Glycosites reported and annotated in the database UniProtKB (<http://www.uniprot.org/>) are annotated as (+). Those which have never been confirmed as glycosylated in UniProtKB are annotated as (-). A glycosite was considered as partially occupied (**PO**) as long as its non-glycosylated form (asparagine) was detected in any sample.

Supplementary Table S6 | The proteomic and glycoproteomic performance of the GlycoFilter platform on three human plasma samples (**P1**, **P2** and **P3**). ^{18}O -incorporated peptides designated those peptides containing deamidated asparagine with one ^{18}O -atom. Deglycopeptides were defined by meeting two criteria: 1) the asparagine was deamidated and incorporated by one ^{18}O -atom, and 2) such specific asparagine was in a N-glycosylation consensus motif “NXS/T” (X is any amino acid except proline).

Sample	Proteins	Peptides	^{18}O -incorporated peptides	Deglycopeptides (NXS/T)	Glycoproteins
P1	306	3556	262	238	115
P2	327	3879	293	259	125
P3	317	3762	251	225	119

Supplementary Table S7 | The complete list of non-redundant N-glycosites (295), spanning in 141 glycoproteins, identified in three biological plasma samples (**P1**, **P2** and **P3**). G: the site was detected as the deglycosylated form only (¹⁸O-incorporated aspartic acid); N: the glycosite was detected as the non-glycosylated form only (asparagine); P: the glycosite was detected as both the non-glycosylated and deglycosylated forms; (-): the glycosite was not detected in specific sample. Glycosites reported in the database UniProtKB (<http://www.uniprot.org/>) are annotated as (+). Those have not been confirmed as glycosylated in UniProtKB are annotated as (-). A glycosite was considered as partially occupied (**PO**) if its non-glycosylated form (asparagine) was detected in any sample.
