**ABSTRACT (300 words):**

**Introduction:** Non-alcoholic steatohepatitis (NASH) is now the commonest cause of chronic liver disease. Despite this, there are no universally accepted pharmacological therapies for NASH. Liraglutide (Victoza®), a human glucagon-like peptide-1 analogue, has been shown to improve weight loss, glycaemic control and liver enzymes in type 2 diabetes. There is currently a lack of prospective-controlled study investigating the efficacy of GLP-1 analogues in patients with NASH.

**Methods and analysis:** LEAN is phase II, multi-centre, double-blinded, placebo-controlled, randomised clinical trial designed to investigate whether 48 weeks treatment with 1.8mg liraglutide will result in improvements in liver histology in patients with NASH. Adult, overweight (body mass index  $\geq 25\text{kg/m}^2$ ) patients with biopsy-confirmed NASH were assessed for eligibility at 5 recruitment centres in the UK. Patients who satisfied the eligibility criteria were randomly assigned (1:1) to receive once-daily subcutaneous injections of either 1.8mg liraglutide or liraglutide-placebo (control). Using A'Hern's single stage phase II methodology (significance level 0.05; power 0.90) and accounting for an estimated 20% withdrawal rate, a minimum of 25 patients were randomised to each treatment group. The primary outcome measure will be centrally assessed using an intention-to-treat analysis of the proportion of evaluable patients achieving an improvement in liver histology between liver biopsies at baseline and after 48 weeks of treatment. Histological improvement will be defined as a combination of the disappearance of active NASH and no worsening in fibrosis.

**Ethics and dissemination:** The protocol was approved by the National Research Ethics Service (East Midlands – Northampton committee; 10/H0402/32) and the

1  
2  
3 MHRA. Recruitment into the LEAN started in August 2010 and ended in May 2013,  
4  
5 with 52 patients randomised. The treatment follow-up of LEAN participants is  
6  
7 currently ongoing and is due to finish in July 2014. The findings of this trial will be  
8  
9 disseminated through peer-reviewed publications and international presentations.

## 1.1 Introduction

Non-alcoholic fatty liver disease (NAFLD) is now the commonest cause of chronic liver disease, affecting up to 30% of the general population (1-3) and 70-90% of high-risk individuals (3, 4). This prevalence relates to the dramatic rise in recent years of morbid obesity and type 2 diabetes. Even though simple hepatic steatosis (without fibrosis) is arguably a benign condition, up to a quarter of patients with NAFLD have the more severe, inflammatory condition known as non-alcoholic steatohepatitis (NASH) (5). Patients with NASH have an increased risk of progression to cirrhosis, liver failure and hepatocellular carcinoma (6), and are expected to become the commonest indication for liver transplantation in forthcoming years (7). Despite this, there are no universally accepted pharmacological therapies for NASH. Therefore the need for novel, safe agents in NASH is of paramount importance to prevent disease progression and the accompanying clinical burden.

The strong association of NASH with the metabolic syndrome, in particular central adiposity and insulin resistance, provides strong rationale for investigating therapies that induce weight loss and insulin sensitivity. The gut-derived incretin hormone, glucagon-like peptide-1 (GLP-1), is therefore an attractive target option in NASH. Native GLP-1 has a potent blood glucose-lowering action mediated via its ability to induce insulin secretion and reduce glucagon secretion in a glucose-dependent manner, as well as suppressing appetite and slowing gastric emptying (8). Human GLP-1, however, only has a short half-life (1.5-2.0 mins) as it is rapidly degraded by the enzyme dipeptidyl peptidase-4 (9). Liraglutide (Victoza®) is a long-acting (half-

1  
2  
3 life 13 hours) GLP-1 analogue with 97% structural homology to the native hormone  
4  
5 and is administered once daily (OD) by subcutaneous injection (10). Liraglutide has  
6  
7 been shown to cause dose-dependent weight loss (11, 12), decrease glycosylated  
8  
9 haemoglobin (HbA1c), systolic blood pressure and improve beta-cell function (13-  
10  
11 18). Subsequently, it has been licensed for glycaemic control in overweight patients  
12  
13 with type diabetes (19). There is, however, a paucity of data in patients with liver  
14  
15 disease, and in particular histological-defined NASH.  
16  
17

18  
19  
20  
21 GLP-1 analogues, including liraglutide, have been shown to improve liver enzymes,  
22  
23 oxidative stress and hepatic steatosis in murine models *in vivo* and in isolated *in vitro*  
24  
25 murine and human hepatocyte studies (20-25). To date, human studies investigating  
26  
27 the effect on liver injury have been limited to case reports (26, 27), solitary case  
28  
29 series (n=8) (28) and retrospective (*liver enzyme*) studies in patients with type 2  
30  
31 diabetes (29). A large meta-analysis of six phase III randomized-controlled trials  
32  
33 (RCT), that comprised the LEAD (Liraglutide Effect and Action in Diabetes) program  
34  
35 (>4000 patients), highlighted that 26-weeks treatment with 1.8mg OD liraglutide was  
36  
37 well-tolerated and resulted in significant improvements in liver enzymes compared  
38  
39 to placebo-control in overweight patients with type diabetes (30). However,  
40  
41 limitations of this study were the retrospective nature of its analysis and the lack of  
42  
43 any liver biopsy data.  
44  
45  
46  
47  
48

49  
50  
51  
52 On this basis, we hypothesised that 48 weeks treatment with liraglutide would result  
53  
54 in significant improvements in liver histology in overweight patients with NASH. To  
55  
56  
57  
58  
59  
60

1  
2  
3 test this hypothesis, we designed a phase II, multi-centre, double-blinded, placebo-  
4  
5 controlled RCT, entitled 'Liraglutide Efficacy and Action in NASH (LEAN).'

## 1.2 Methods

### 1.2.1 Study Design Overview

LEAN is a 48 week multi-centre, double-blinded, placebo-controlled randomised clinical trial of treatment with the once daily human GLP-1 analogue, liraglutide (Victoza®), for adults with biopsy-proven NASH. Screening was undertaken within 14 days of randomisation to assess eligibility and collect baseline data. Patients who satisfied the eligibility criteria were randomly assigned (1:1) to receive OD subcutaneous injections of either 1.8 mg liraglutide (experimental) or liraglutide-placebo (control). After which, a 12-week washout period is scheduled.

The primary outcome measure will be assessed using an intention-to-treat analysis of the proportion of evaluable patients achieving an improvement in liver histology between liver biopsies at baseline (within 6 months of screening) and after 48 weeks of treatment. Histological improvement will be defined as a combination of the disappearance of active steatohepatitis (i.e. disappearance of hepatocyte ballooning) and no worsening in fibrosis (Kleiner Fibrosis score (31)). A schematic of the trial design is summarised in **Figure 1**.

### 1.2.2 Ethical and regulatory approval

The National Research Ethics Service (NRES) East Midlands – Northampton committee (previously known as Leicestershire, Northamptonshire and Rutland

1  
2  
3 Research Ethics Committee) (UK) and the Medicines and Healthcare products  
4  
5 Regulatory Agency (MHRA) approved all versions (inc. current version 7.0) of the  
6  
7 study protocol. In addition, all 5 recruitment sites obtained approval from their  
8  
9 respective hospital Research and Development (R&D) departments prior to  
10  
11 commencing screening.  
12

### 13 14 15 16 **1.2.3 Treatment groups** 17

18  
19  
20 Patients who satisfied the eligibility criteria were randomly assigned on a 1:1 basis to  
21  
22 48-weeks treatment of either liraglutide (Victoza®; 1.8mg OD) or liraglutide-placebo  
23  
24 control (1.8mg OD).  
25  
26  
27

#### 28 29 30 *1.2.3.1 Liraglutide (active experimental group)* 31

32  
33  
34 Liraglutide (Victoza®, Novo Nordisk A/S, Bagsvaerd, Denmark) was supplied in a  
35  
36 cartridge contained in a pre-filled multi-dose disposable pen. Each pre-filled pen  
37  
38 contained 18 mg liraglutide in 3 ml of clear, colourless, isotonic solution (including  
39  
40 water for injections, disodium phosphate dehydrate, propylene glycol and phenol).  
41  
42 Liraglutide was administered OD, at any time of the day, as a single subcutaneous  
43  
44 injection into the abdomen, thigh or upper arm using the pre-filled pen (30 or 31  
45  
46 gauge needles). Participants were encouraged to inject liraglutide at the same time  
47  
48 each day, according to which was the most convenient time for them. Participants  
49  
50 were instructed to perform an air shot of 0.2 µl before the first use of each new pre-  
51  
52 filled pen to ensure that it functioned correctly.  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 To improve gastro-intestinal tolerability participants underwent a 14-day dose  
4 titration period in keeping with previous reports (13-18). The dose was titrated by  
5  
6 0.6 mg every 7 days from a starting dose of 0.6mg OD until the maximum dose of 1.8  
7  
8 mg OD was achieved. Prior to the current trial design, no studies had investigated  
9  
10 any form of GLP-1 based therapy in patients with biopsy-confirmed NASH or any  
11  
12 other form of liver disease. Therefore, the rationale for using a dose of 1.8mg OD  
13  
14 was based upon previous reports in overweight patients with or without type 2  
15  
16 diabetes (13-18). Furthermore, a large meta-analysis of six phase III clinical trials  
17  
18 (LEAD program) of liraglutide therapy for poorly controlled type 2 diabetes found  
19  
20 that patients with abnormal liver transaminases had a similar drug safety profile to  
21  
22 those with normal liver transaminases. In addition, greater improvements in liver  
23  
24 transaminases and CT-measured hepatic steatosis were seen with 1.8mg liraglutide  
25  
26 than 1.2 and 0.6mg doses (30).  
27  
28  
29  
30  
31  
32  
33  
34  
35

### 36 *1.2.3.2 Liraglutide-placebo (inactive, placebo-control group)*

37  
38  
39 Liraglutide-placebo (Victoza®, Novo Nordisk A/S, Bagsvaerd, Denmark) was  
40  
41 packaged, administered and dose-titrated in an identical manner to the liraglutide  
42  
43 comparator, described above. The composition of the placebo solution for injection  
44  
45 was identical to its comparator, with the exclusion of the active liraglutide  
46  
47 substance. A placebo was used to provide an assessment of the level of response  
48  
49 with an injectable placebo, which could potentially be higher than that seen with  
50  
51 oral placebo agents.  
52  
53  
54  
55  
56  
57  
58  
59  
60

### 1.2.3.3 Concomitant Therapy

No dose reductions of liraglutide or placebo were allowed throughout the 48 week treatment period. Previous treatment with oral anti-diabetic drugs (metformin and/or sulphonylurea) was continued at the same dose in participants with type 2 diabetes at randomisation. In the event of recurrent major hypoglycaemic episodes (requiring medical or hospital intervention), the dose of the sulphonylurea was reduced by 50% at the discretion of the investigators. The reported rate of hypoglycaemia in the literature, with liraglutide monotherapy or in combination with metformin, is very low (13-18). However in the event of recurrent major hypoglycaemic episodes in which no dose reduction could be undertaken (i.e. not on a sulphonylurea) the subject was withdrawn from treatment at the discretion of the chief investigator.

Glycaemic control was assessed at each 12-weekly trial visit with self-measured plasma glucose readings and HbA1c. In the event that glycaemic control deteriorated, defined as HbA1c > 9.0% (75 mmol/mol), the subject was informed and counselled with regards to commencing open-labelled long-acting OD insulin detemir (Levemir®). However, the patient's participation in the trial was not jeopardised if they did not wish to start insulin detemir. The Insulin detemir dose was titrated by trial investigators in accordance with European guidelines ([www.ema.europa.eu](http://www.ema.europa.eu)) to ensure that the subject's standard of diabetes care was not significantly compromised as a result of participating in the clinical trial. The HbA1c cut-off of >9.0% was based on the opinions of the TMG (MJA, PNN),

1  
2  
3 consisting of expert endocrinologists (SG, JWT), and in accordance with previous  
4  
5 clinical trial guidance (32).  
6  
7  
8  
9

10 In addition to study medications, participants continued to receive standard National  
11  
12 Health Services (NHS) care recommendations concerning life-style modifications (i.e.  
13  
14 exercise, weight loss and dietary modification) and management of various co-  
15  
16 existing illnesses throughout the trial. Patients were asked to limit alcohol  
17  
18 consumption to less than 20 mg/day for females (i.e. 14 units/week) and 30 mg/day  
19  
20 for males (i.e. 21 units/week). These levels were consistent with the UK  
21  
22 Departmental of Health recommended daily alcohol allowance (British Medical  
23  
24 Association 1995). Participants were not allowed any new prescription or over-the-  
25  
26 counter therapies (i.e. herbal remedies, milk thistle) that may improve or worsen  
27  
28 NASH throughout the duration of the trial. Potential NASH therapies that were not  
29  
30 allowed during the trial duration included thiazolidinediones (TZDs), dipeptidyl  
31  
32 peptidase (DPP) IV inhibitors, other GLP-1 receptor agonists (e.g. exenatide), vitamin  
33  
34 E and orlistat. Steroids (oral or intravenous), methotrexate and/or amiodarone were  
35  
36 also not permitted based on their ability to promote hepatic steatosis.  
37  
38  
39  
40  
41  
42  
43  
44

#### 45 **1.2.4 Outcome Measures**

##### 46 47 48 49 *1.2.4.1 Primary Outcome Measure*

50  
51  
52  
53  
54  
55 The primary outcome measure is the proportion of participants with a significant  
56  
57 improvement in liver histology between liver biopsies at baseline (i.e. within 6  
58  
59  
60

1  
2  
3 months of screening) and at the end of 48-weeks treatment. The definition of a  
4  
5 significant histological improvement requires both the disappearance of  
6  
7 steatohepatitis (defined as a disappearance of hepatocyte ballooning) and no  
8  
9 worsening of fibrosis, as assessed by the Kleiner scoring system (31). Hepatocyte  
10  
11 ballooning is now widely recognised as the key lesion for distinguishing NASH from  
12  
13 simple steatosis.  
14  
15

#### 16 17 18 19 *1.2.4.2 Secondary Outcome Measures* 20

21  
22  
23  
24 Secondary outcome measures include changes in; (a) overall NAFLD Activity Score  
25  
26 (NAS) (31); (b) individual histological components of NAS, including lobular  
27  
28 inflammation, steatosis, hepatocyte ballooning, and fibrosis; (c) serum markers of  
29  
30 steatosis (SteatoTest™), NASH (NashTest™, caspase-cleaved cytokeratin-18 [CK-18  
31  
32 M30]), and fibrosis (Enhanced Liver Fibrosis (ELF; iQUR Ltd), FibroTest™); (d) Liver  
33  
34 stiffness evaluation (LSE) with Transient Elastography (Fibroscan®, Echosens, Paris,  
35  
36 France); (e) Insulin resistance (HOMA-IR); (f) Anthropometric measures including  
37  
38 body weight, body mass index (BMI) and waist circumference; (g) Lipid profile and  
39  
40 glycaemic control (HbA1c, fasting plasma glucose); (h) serum ALT levels; and (i)  
41  
42 health-related quality of life (SF-26 version 2.0) and nutrition (Block Brief 2000 Food  
43  
44 Frequency Questionnaire questionnaires).

## 1.2.5 Analytical Methods

### 1.2.5.1 Liver Histopathology

Two independent liver histopathologists (SGH, RB) at the central trial site (Birmingham, UK) will perform all the histopathological assessments using an in-house designed proforma (**Supplementary table 1**). Both histopathologists will be blinded to the clinical, laboratory and study treatment allocation. The histological diagnosis of NASH will be established using haematoxylin and eosin (H&E) staining and haematoxylin van Gieson stains of formalin fixed paraffin-embedded liver tissue. Both the baseline and end of treatment (48 weeks) biopsies will be reported as either 'definite NASH,' 'uncertain NASH,' or 'not NASH.' The histological diagnosis of 'definite NASH' is defined as a combination of >5% macrovesicular steatosis, hepatocyte ballooning (+/- Mallory's Hyaline) and lobular inflammation (mixed infiltrate, related to foci of ballooning) (33). The assessment of ballooning is subjective, and thus for 'uncertain' hepatocyte ballooning, a key component of the diagnosis of NASH, ubiquitin immunohistochemistry will be used to identify material compatible with Mallory's hyaline (**Figure 2**). To validate the quality of the biopsy specimen the core specimen length will be measured and the number of portal tracts will be recorded.

The NAS will be calculated based on the Kleiner classification (31). The NAS is score out of 8, with 8 representing the highest activity. The NAS is the sum of scores of the three components of the histological scoring system, namely steatosis (0 = < 5%, 1 =

1  
2  
3 5-33%, 2 = >33-66%, 3 = >66%), lobular inflammation (0 = no foci, 1 = <2 foci/200x, 2  
4 = 2-4 foci/200x, 3 = >4 foci) and hepatocyte ballooning (0= none, 1 = few ballooned  
5 cells, 2 = many cells/prominent ballooning). The Kleiner scoring system for NAFLD  
6 fibrosis (F0-F4) (31) and a modified version of the Ishak score (34) (F0-F6)  
7  
8 **(Supplementary table 1)** will be used to evaluate the stage of fibrosis in each biopsy  
9 specimen. The Ishak score was modified from the original scoring system, reported  
10 in 1995 (34), in order to include the zone 3 peri-cellular/peri-sinusoidal fibrosis,  
11 which is characteristically seen in NASH. Portal tract changes (inflammation,  
12 interface hepatitis, ductular reaction), an intrinsic feature of NASH, will also be  
13 recorded (35).  
14  
15  
16  
17  
18  
19  
20  
21  
22  
23  
24  
25  
26  
27

28 The pathologists will assess the biopsies independently and fill in separate forms.  
29 Cases where there is disagreement on the classification, as 'NASH' or 'not NASH,' will  
30 be reviewed and a consensus opinion given. Also discrepancies of more than 1 point  
31 on any of the scoring scales (NAS, Kleiner fibrosis scoring system and modified Ishak  
32 score) will be reviewed and an amended consensus view offered. Discrepancies of  
33 only 1 point will not be altered.  
34

43  
44

#### 45 *1.2.5.2 Clinical and Laboratory data*

46  
47  
48  
49 Fasting blood samples will be analysed for full blood count, urea, creatinine and  
50 electrolytes, thyroid stimulating hormone (TSH), lipid profile (total cholesterol, HDL,  
51 triglycerides), liver function tests (LFT), prothrombin time, International Normalised  
52 Ratio (INR), amylase, alpha-feta protein (AFP), c-reactive protein (CRP), glycosylated  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 haemoglobin (HbA1c), calcitonin and plasma glucose using standard laboratory  
4  
5 methods (Roche Modular system, Roche Ltd, Lewes, UK). Serum Insulin (Merckodia,  
6  
7 Uppsala, Sweden), non-esterified fatty acids (NEFA) (Zen-Bio, Research Triangle Park,  
8  
9 NC, USA) and CK-18 M30 (M30 Apoptosense ELISA Kit; PEVIVA AB, Bromma, Sweden)  
10  
11 will be measured in-house using commercially available colorimetric ELISAs. Serum  
12  
13 caspase-cleaved cytokeratin-18 (CK-18 M30) and the Enhanced Liver Fibrosis (ELF)  
14  
15 Test were performed at study entry to assess hepatic apoptosis and fibrosis,  
16  
17 respectively. The FibroMax™ panel (consisting of the SteatoTest™, NashTest™,  
18  
19 FibroTest™) will be undertaken by Lab 21 Ltd (Cambridge, UK). The ELF test, which  
20  
21 combines three direct serum markers of fibrosis (hyaluronic acid, pro-collagen III  
22  
23 amino terminal peptide and tissue inhibitor of metalloproteinase 1) using an  
24  
25 algorithm developed by the European Liver Fibrosis Group (36), will be performed on  
26  
27 fasting serum stored at -80 degrees by a commercial laboratory (iQUR Ltd, Royal  
28  
29 Free Hospital, London, UK).  
30  
31  
32  
33  
34  
35  
36  
37

38 Type 2 diabetes was considered present if patients had a recorded diagnosis in their  
39  
40 medical records or if the fasting plasma glucose was  $\geq 7.0$  mmol/L and/or if the 2-  
41  
42 hour 75g oral glucose tolerance test (OGTT) plasma glucose was  $\geq 11.1$  mmol/L. All  
43  
44 patients without a recorded history of T2D were screened with an OGTT. Impaired  
45  
46 glucose tolerance was defined as a 2-hour plasma glucose between 7.8 and 11.1  
47  
48 mmol/L. HOMA-IR, a marker of insulin resistance, was calculated in the standard  
49  
50 fashion:  $\text{Glucose} \times \text{Insulin} \div 22.5$ .  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 Measurements of weight (kg), height, systolic/diastolic blood pressure and waist:hip  
4  
5 circumferences were recorded. Waist and hip circumferences were defined as the  
6  
7 circumferential measurements immediately above the level of the iliac crests and at  
8  
9 the level of the greater trochanters, respectively. Body mass index (BMI) was defined  
10  
11 as weight in kilograms divided by the square of the height in metres ( $\text{kg}/\text{m}^2$ ).  
12  
13

14  
15  
16 Liver stiffness evaluation (LSE) was measured using Transient Elastography  
17  
18 (Fibroscan®, Echosens, France). The median value and interquartile range (IQR) of  
19  
20 10 validated measurements were recorded within the range of 2.5 to 75 kPa. The XL  
21  
22 probe was used on individuals who have a BMI greater than  $30 \text{ kg}/\text{m}^2$  or when the  
23  
24 Fibroscan® 502 Touch machine (automated) recommends its use over the M-probe.  
25  
26 To achieve a valid LSE (median of successful liver stiffness measurements) the  
27  
28 operator had to obtain all of the following 3 criteria: 1)  $\geq 10$  successful liver stiffness  
29  
30 measurements; 2) IQR/median ratio  $< 0.30$ ; and 3)  $\geq 60\%$  measurement success rate  
31  
32  
33  
34  
35  
36 (37).  
37  
38  
39

#### 40 41 *1.2.5.3 Patient questionnaires* 42 43 44

45  
46 Quality of life (QOL) was assessed by the Short Form 36 version 2.0 (SF-36v2) health-  
47  
48 related QOL questionnaire (QualityMetric Health Outcomes Solutions, Lincoln, USA).  
49  
50 The SF-36v2 questionnaire was a practical, reliable and valid measure of physical and  
51  
52 mental health that could be completed in 5-10 mins. It consisted of 36 questions  
53  
54 that assessed the functional health and well-being from the study subject's point of  
55  
56 view (38). The Block Brief 2000 Food Frequency Questionnaire (FFQ) (Block Dietary  
57  
58  
59  
60

1  
2  
3 Data Systems, California, US) was completed by each subject to assess usual and  
4  
5 customary intake of a wide array of nutrients and food groups. The food list  
6  
7 incorporated in the Block questionnaire was developed from the National Health and  
8  
9 Nutrition Examination Survey (NHANES) III dietary recall data. The Block Brief 2000  
10  
11 FFQ consisted of a well-validated self-administered questionnaire consisting of 70  
12  
13 food related questions and took approximately 15 mins to complete (39). Pictures of  
14  
15 standardized serving sizes and an American-to-English food translation sheet (i.e.  
16  
17 'Catsup' = tomato 'Ketchup') were used to aid completion of the questionnaire.  
18  
19

20  
21  
22  
23  
24 The Alcohol Use Disorder Identification Test (AUDIT) questionnaire was used to  
25  
26 assess the frequency of alcohol consumption and screen out alcohol-related  
27  
28 problems, and dependence symptoms (40). The AUDIT questionnaire consisted of a  
29  
30 10-item questionnaire that took 2-5 mins to complete. The questionnaire has a  
31  
32 positive predictive value of 98% for hazardous drinking, and a negative predictive  
33  
34 value of 97% for alcohol dependence. The overall score ranges from 0 to 40, with a  
35  
36 score of less than 8 being a good indication of insignificant alcohol consumption.  
37  
38  
39

40  
41  
42 All questionnaires were completed at baseline (visit 1), end of treatment (visit 7) and  
43  
44 12 weeks post treatment (visit 8). Analysis will report the change from baseline  
45  
46 scores to both the end of treatment and follow up scores.  
47  
48  
49

58  
59  
60

## 1.2.6 Statistical Justification and Outcome Analysis

### 1.2.6.1 Sample size Justification

This is an early phase II trial randomising patients equally between two treatment arms - one experimental (liraglutide) and one control (placebo). The primary aim is not to determine the efficacy of liraglutide compared to placebo but to assess whether the efficacy and safety profile of liraglutide is worthy of further investigation. Recruiting patients into a no treatment control group provides simultaneous unbiased assessment of comparable patient groups.

At the time of the study design there were no available data to estimate histological response with 48 weeks treatment of liraglutide (Victoza®). Based on previous non-GLP-1 pharmaceutical trials in NASH utilising improvements in liver histology as a primary end-point (41, 42), it was assumed that 14-17% of patients undergoing current standard of care (placebo) would have an improvement in NASH by week 48. It was estimated that 20% of the placebo-control arm would achieve an improvement in liver histology, based in part on the knowledge that the placebo-effect might be exaggerated by the subcutaneous injection route of administration (vs. oral route in previous NASH trials) in the current trial. To justify further investigation of liraglutide treatment, a clinically relevant improvement in liver histology was required in at least 50% of patients. The sample size was calculated using A'Hern's single stage phase II methodology (43), with a significance level of 0.05 (type 1 error) and power of 0.90 (type II error). The design required 21

59  
60

evaluable patients in the treatment group. The published literature in NASH trials reported on average a participant withdrawal rate of 10-20% (41, 42, 44). Therefore, to account for a 20% withdrawal rate the recruitment target was inflated from 21 to 25 patients per treatment group; the total recruitment target being 50 patients randomised in a 1:1 allocation ratio to either Liraglutide or placebo.

### 2.5.2 Analysis of Outcome Measures

All evaluable patients will be analysed on the intention-to-treat principle. Evaluable patients are defined as those who have had an end of treatment biopsy (visit 7), irrespective of the amount of treatment they have received. Patients will be categorised as either achieving the primary histological end-point (i.e. disappearance in NASH) or not. The proportion of patients with a reported improvement in liver histology will be presented and compared across treatments descriptively with 95% confidence intervals. The proposed A'Herns design stipulates that 8 or more evaluable patients out of 21 in the experimental treatment group (liraglutide) need to achieve the defined improvement in liver histology for treatment with liraglutide to be deemed worthy of further investigation with a phase III trial. Analyses will be presented for the subgroups of patients with and without type 2 diabetes. Patients who have not had an end of treatment biopsy will be classed as non-evaluable and will not be included in the primary analysis.

Secondary analysis of the primary outcome measure will report (a) the numbers and proportion of patients that did not have an end of treatment biopsy and the reasons

1  
2  
3 for this (these will be classified as 'no histological improvement') and (b) the  
4  
5 numbers and proportion of patients that were considered to have had sufficient  
6  
7 treatment and an end of treatment biopsy. In addition, an analysis that directly  
8  
9 compares the two proportions for the separate treatment arms will be performed  
10  
11 using the Chi-squared test.  
12  
13

14  
15  
16  
17 Secondary measures collected as continuous and categorical variables will be  
18  
19 presented with 95% confidence intervals descriptively across treatments using  
20  
21 medians and proportions, respectively. Secondary measures collected as longitudinal  
22  
23 data (including quality of life data, scored as per the questionnaire specific scoring  
24  
25 manuals) will be presented descriptively across treatment groups as changes over  
26  
27 time. A summary of all adverse events experienced by patients in both arms will be  
28  
29 reported.

### 1.3 Conduct of the trial

#### 1.3.1 Patient Selection

Eligible adults ( $\geq 18$  years old) were identified and recruited at the participating trial site centres starting in August 2010 and by May 2013, 52 patients were recruited. Participating UK trial centres included the liver units at the Queen Elizabeth University Hospital (Birmingham, from Aug 2010), Queens Medical Centre (Nottingham, from May 2011), Southampton General Hospital (Southampton, Sept 2011), Hull Royal Infirmary (Hull, Nov 2011) and St. James Hospital (Leeds, from May 2012). All trial participants gave informed written consent at the beginning of the screening visit prior to undergoing any tests and procedures needed to assess eligibility.

Eligibility for the trial was determined at screening visit 1 by standard blood tests, clinical history (including written-confirmation of drug history where necessary) and physical examination/observations to identify other illnesses or contraindications for participation (Trial schedule figure). In addition, after receiving formal training the patient's ability to understand and self-administer the subcutaneous injections using the pre-filled treatment pen was assessed by an experience nurse specialist at screening visit 2. Patients who satisfied the eligibility criteria for the 48 week treatment trial at the Birmingham site were given the option to participate in a metabolic mechanistic sub-study. The sub-study involved two overnight admissions (approximately 22 hours) to the Wellcome Trust Clinical Research Facility

1  
2  
3 (Birmingham) to undergo a 2-step hyperinsulinaemic euglycaemic clamp with stable  
4  
5 isotopes and adipose microdialysis on visits 2 (pre-treatment) and visit 4 (12-weeks  
6  
7 treatment). A detailed summary of the metabolic sub-study will be published  
8  
9 separately. A patient's decision to partake or withdraw from the metabolic sub-study  
10  
11 did not affect their participation in the main 48 week trial.  
12  
13

#### 14 15 16 17 *1.3.1.1 Inclusion Criteria* 18 19

20  
21 The trial entry criteria were based on a diagnosis of 'definite' NASH on liver biopsy  
22  
23 obtained within 6 months of screening. Prior to randomisation, two independent  
24  
25 liver histopathologists (SGH, RB) from the central trial site (University Hospital  
26  
27 Birmingham, UK) reviewed all of the liver biopsies (internal and external trial sites) of  
28  
29 the potential participants to assess whether a diagnosis of 'definite' NASH was  
30  
31 present. A 'definite' diagnosis of NASH was defined if all of the following were  
32  
33 present on biopsy: (i) macrovesicular steatosis (>5%); (ii) hepatocyte ballooning (+/-  
34  
35 Mallory Hyaline); and (iii) Lobular inflammation (mixed infiltrate, related to foci of  
36  
37 ballooning). The two independent histopathology case report forms (CRFs) were  
38  
39 reviewed by a trial investigator (MJA) and in the event that the histopathologists  
40  
41 disagreed with regards to the diagnosis of NASH (i.e. one judged 'uncertain' and the  
42  
43 other 'definite') a combined histopathology assessment was undertaken to  
44  
45 determine the patient's eligibility status. Only patients with 'definite' NASH (either  
46  
47 on two independent reports or after joint review) were classified as eligible.  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 All participants had to be  $\geq 18$  to  $< 70$  years old and have a body mass index (BMI)  $\geq$   
4  
5  $25 \text{ kg/m}^2$  at screening. Patients with Type II Diabetes Mellitus at screening had to  
6  
7 have stable glycaemic control (HbA1c  $< 9.0\%$ ) and be managed by either diet and/or  
8  
9 a stable dose of metformin/sulphonylurea. Patients without a history of type 2  
10  
11 diabetes prior to the screening visit underwent an OGTT at screening to determine  
12  
13 their glycaemic status and were labelled as 'non-diabetic' if one or more of the  
14  
15 following was confirmed:  
16  
17

- 18 ❖ Impaired fasting glucose (IFG), defined using the European Criteria between  
19  
20 6.1 and 6.9 mmol/L  
21  
22
- 23 ❖ Impaired glucose tolerance (IGT), defined as two-hour plasma glucose levels  
24  
25 between 7.8 and 11.0 mmol/L on the 75-g OGTT  
26  
27
- 28 ❖ Normal Fasting Plasma Glucose (FPG)  $< 6.1$  mmol/L and Normal 2-hour  
29  
30 plasma glucose levels  $< 7.8$  on the 75g OGTT.  
31  
32

### 33 34 35 36 *1.3.1.2 Exclusion Criteria*

37  
38  
39  
40  
41 A detailed summary of the exclusion criteria is provided in **Table 1**. In brief, patients  
42  
43 with a history or current significant alcohol consumption, poor glycaemic control  
44  
45 (HbA1c  $> 9.0\%$ ), Child's Pugh B or C cirrhosis or another liver disease aetiology were  
46  
47 excluded. The latter was confirmed with a full liver aetiology screen (drug-induced,  
48  
49 viral hepatitis B/C, autoimmune, and genetic) at the screening visit. Past and current  
50  
51 alcohol consumption was ascertained by a detailed review of the patients past  
52  
53 medical, social history and by a self-administered AUDIT questionnaire with  
54  
55 reference pictures to remind subjects of drink equivalents. Concomitant use of drugs  
56  
57  
58  
59  
60

1  
2  
3 reported to be inducers (methotrexate, amiodarone, steroids) or potential therapies  
4  
5 for NASH (TZDs, vitamin E), or other known hepatotoxins were assessed during the  
6  
7 screening visit (**Table 1**). In keeping with previous clinical trials assessing GLP-1  
8  
9 therapies, patients with a history of acute/chronic pancreatitis (of any cause),  
10  
11 pancreatic and thyroid carcinoma, and/or a family history of medullary thyroid  
12  
13 carcinoma were also excluded.  
14  
15

### 16 17 18 19 **1.3.2 Randomisation**

20  
21  
22  
23  
24 Subjects who met all the eligibility criteria and provided written informed consent  
25  
26 were randomly assigned on a 1:1 basis to either of the two study treatments  
27  
28 (liraglutide vs. placebo) using computer generated randomisation at the Cancer  
29  
30 Research UK Clinical Trials Unit (CRCTU). The randomisation was stratified to ensure  
31  
32 that there were equal numbers of patients with/without type 2 diabetes in each  
33  
34 treatment group and that each trial site had equal numbers of patients on each  
35  
36 treatment. Trial subjects were allocated a unique trial identification number to  
37  
38 preserve patient confidentiality and enable the study to be double-blinded.  
39  
40  
41  
42  
43  
44

### 45 **1.3.3 Medication preparation and blinding/unblinding procedures:**

46  
47  
48  
49 Both liraglutide and placebo-control were packaged and labelled with a unique  
50  
51 identification number (in keeping with the European Unions Good Manufacturing  
52  
53 Practice for Medicinal Product guidelines) in by the manufacturer (Novo Nordisk  
54  
55 Ltd), to the extent that the receiving trial site was blinded to the study drug  
56  
57  
58  
59  
60

1  
2  
3 throughout the duration of the trial. Sealed parcels (containing electronic  
4  
5 information) were sent with each drug package for the attention of the unblinded  
6  
7 members of the central trial management group (TMG) (nominated statistician, PG  
8  
9 and database programmer, PM, to ensure a) safe delivery of the correct drug and b)  
10  
11 blinding of the treatment allocation from the remainder of the TMG and the trial  
12  
13 patient. An independent unblinding service (24/7) was provided by the Medical  
14  
15 toxicology and Information services, Guys hospital (London, UK), throughout the  
16  
17 duration of the trial.  
18  
19

20  
21  
22  
23  
24 Unblinding of treatment only take place if the identity of the allocated study  
25  
26 medication was necessary for patient safety and care. If a serious adverse event  
27  
28 (SAE) was deemed unexpected and possibly, probably or definitely related to  
29  
30 liraglutide (i.e. suspected unexpected serious adverse reaction = SUSAR), a clinical  
31  
32 member of the TMG was unblinded to the medication to evaluate causality.  
33  
34 Subsequently, the event was either labelled as an unrelated SAE (for patients  
35  
36 receiving placebo) or a SUSAR (for patients receiving liraglutide). The latter were  
37  
38 reported to the MHRA and the NRES, and only if patient safety was jeopardised was  
39  
40 the study medication discontinued and the treating clinician/patient informed.  
41  
42  
43  
44  
45  
46

#### 47 **1.3.4 Adverse event (AE) reporting and analysis**

48  
49  
50

51  
52 The reporting period for AEs commenced at screening visit 1 and continued until  
53  
54 follow-up visit 8. SAEs were reported until day 336 (week 48) of the trial treatment  
55  
56 and for 30 days post-EOT. All SAEs and adverse reactions were evaluated by the  
57  
58  
59  
60

1  
2  
3 investigators and recorded. The National Cancer Institute's common terminology  
4  
5 criteria for AEs (CTCAE, version 4.02, 2010) was used to grade each AE. The central  
6  
7 trial office (CRCTU, Birmingham) kept detailed records of all AEs reported (nature,  
8  
9 onset, duration, severity, outcome) and performed an evaluation with respect to  
10  
11 seriousness, causality and expectedness. Interim analysis of safety data was  
12  
13 performed and presented to the independent data management committee (DMC)  
14  
15 on a 6-monthly basis. The unblinded DMC advised accordingly with regards to the trial  
16  
17 conduct and specifically whether extra/new data monitoring was required for the  
18  
19 remainder of the trial. The DMC operated in accordance with a trial specific charter  
20  
21 based upon the template created by the Damocles Group. Specific attention was  
22  
23 given to AEs related to the thyroid (measures of blood calcitonin, TSH and physical  
24  
25 examination) and pancreas (blood amylase, symptom recognition for pancreatitis), in  
26  
27 light of previous non-human (rodents) and post-marketing human safety data (in  
28  
29 patients with diabetes), respectively (45, 46).  
30  
31  
32  
33  
34  
35  
36  
37

### 38 **1.3.5 Study visit overview**

39  
40  
41  
42 The LEAN trial involved 8 patient-related visits at their nearest trial site. The study  
43  
44 was divided into four stages: (1) screening, enrolment, randomisation and baseline  
45  
46 investigations (visits 1 and 2, over a maximum period of 14 days), (2) 336 days of  
47  
48 study treatment (visits 3,4,5 and 6, over 48 weeks), (3) Primary end-point  
49  
50 assessment including liver biopsy (visit 7, within 1 day of the EOT), and (4) post-  
51  
52 treatment follow-up assessment (visit 8, 12 weeks after EOT). If the trials  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 investigating team or the trial participant suspected an adverse event, an  
4  
5 unscheduled visit was arranged within 24 hours.  
6  
7

8  
9  
10 The schedule for the study visits and data collection is summarised in **Table 2**. All  
11  
12 subjects were asked to attend each visit fasted from eating or drinking (with  
13  
14 exception of water) for a minimum of 8 hours prior to each visit. A follow-up liver  
15  
16 biopsy (i.e. primary end-point) was obtained under ultrasound-guidance after  
17  
18 completion of 48 weeks study treatment. Wherever possible, a 16-gauge biopsy  
19  
20 needle and a specimen length of a minimum of 15 mm were preferred. The liver  
21  
22 tissue was prepared at the local trial sites in preparation for histological assessment  
23  
24 (under light microscopy) at the central trial site at the Queen Elizabeth University  
25  
26 Hospital Birmingham. On receipt, the two central 'blinded' central histopathologists  
27  
28 recorded the size and quality of the histology slides. A minimum of four unstained  
29  
30 slides was available for each liver biopsy to enable repeat staining (H&E,  
31  
32 haematoxylin van Gieson, Ubiquitin) to ensure adequate quality for interpretation.  
33  
34  
35  
36  
37  
38  
39

#### 40 **1.3.6 Storage of trial samples**

41  
42  
43  
44

45 Liver biopsy tissue specimens were collected, paraffin-fixed and stored at the  
46  
47 diagnostic archive of the department of cellular pathology (University Hospital  
48  
49 Birmingham). Serum and plasma samples collected at visit 1 (screening), visit 4, visit  
50  
51 5, visit 7 (EOT) and visit 8 (12 weeks post EOT) were stored frozen in 0.5-1.0ml  
52  
53 aliquots at -80°C at the Institute of Biomedical Research, University of Birmingham.  
54  
55  
56  
57 Where possible, additional blood (buffer coat) were obtained at visits 1 and 7 for  
58  
59  
60

1  
2  
3 future DNA extraction and stored at -80°C. Both specimen storage banks hold a  
4  
5 licence from the Human Tissue Authority to store tissue for research purposes.  
6  
7  
8  
9

### 10 **1.3.7 Treatment compliance**

11  
12  
13  
14  
15 Treatment compliance was monitored by a review of the used pre-filled treatment  
16  
17 pens, participant injection sites, and the participants self-filled 'standardised  
18  
19 treatment and clinical events booklet' at each study visit. The latter provided written  
20  
21 evidence of dosage, time and date when each patient administers the study drug.  
22  
23  
24  
25

### 26 **1.3.8 Data handling, quality assurance, record keeping and retention**

27  
28  
29  
30  
31 Data management was undertaken according to the standard operating procedures  
32  
33 (SOPs) of the CRCTU at the University of Birmingham, UK. The CRCTU was fully  
34  
35 compliant with the Data Protection Act 1998 and the International Conference on  
36  
37 Harmonisation Good Clinical Practice (ICH GCP). The CRCTU was responsible for  
38  
39 monitoring the trial and providing annual reports to the MHRA. The trial was  
40  
41 registered with the Data Protection Act website at the University of Birmingham.  
42  
43 Participant identifiable data were shared only within the clinical team on a need-to-  
44  
45 know basis to provide clinical care, and to ensure good and appropriate follow-up.  
46  
47  
48 Patient identifiable data were also shared with approved auditors from the NRES,  
49  
50 Competent authorities (including MHRA, EMA and FDA), Sponsor (University of  
51  
52 Birmingham), NHS R&D departments and the primary care practitioner. All LEAN  
53  
54 participants provided specific written-consent at trial entry to enable data to be  
55  
56  
57  
58  
59  
60

1  
2  
3 shared with the above. Otherwise, confidentiality was maintained throughout the  
4  
5 trial and thereafter. On completion of the trial, data will be transferred to a secure  
6  
7 archiving facility at the University of Birmingham, where data will be held for a  
8  
9 minimum of 10 years and then destroyed.  
10

### 11 12 13 14 **1.3.9 Case Report Forms** 15

16  
17  
18 Case report forms included baseline/follow-up medical history and physical  
19  
20 examinations to capture co-morbidities and concomitant medications in the trials  
21  
22 electronic database. Other case report forms incorporated in the electronic database  
23  
24 included: laboratory tests and questionnaire results were recorded for visit 1  
25  
26 (eligibility criteria) through to visit 8; safety monitoring during the treatment follow-  
27  
28 up periods; central site histopathology reports of liver biopsy specimens; specialist  
29  
30 non-invasive markers of liver disease; adverse event reporting; and study drug  
31  
32 dispensing forms for study treatment adherence and accountability.  
33  
34  
35  
36  
37  
38  
39

### 40 **1.3.10 Sponsorship, Indemnity and Monitoring** 41

42  
43  
44  
45 The University of Birmingham acted as the sponsor of the trial. As sponsor the  
46  
47 University was responsible for the general conduct of the study and indemnified the  
48  
49 trial centre against any claims, arising from any negligent act or omission by the  
50  
51 University in fulfilling the sponsor role in respect of the study. Both on-site and off-  
52  
53 site monitoring of the trial were performed as per the LEAN Trial Quality  
54  
55 Management Plan.  
56  
57  
58  
59  
60

### 1.3.11 Sources of funding

The trial was funded by the Wellcome Trust (Clinical Research Fellowship awarded to MJA, 200), Novo Nordisk Ltd (free study drug supply, educational grant) and the NIHR liver BRU.

For peer review only

#### 1.4 Trial status

Recruitment into the LEAN trial commenced in August 2010 and ended in May 2013, with 52 patients (104% of target enrolment) randomised from 5 trial sites (Birmingham 31; Nottingham 12; Hull 6; Leeds 3; Southampton 0). This number is 2 more than planned so as to allow all participants that had registered/consented and found to be eligible to participate in the trial. **Supplementary figure 2** summarises the recruitment rate throughout the trial. A total of 73 patients were registered for the trial, 21 (29%) of whom were not eligible or withdrew consent before randomisation to the trial. Failure to meet the histological inclusion criteria (after central histopathology review) was the most frequent reason for ineligibility. The treatment follow-up of LEAN participants is currently ongoing and the last trial visit of the last participant is due to take place in July 2014.

## 1.5 Discussion

Compliance with the trial protocol and safety profile of liraglutide was reviewed on a bi-annual basis by an independent DMC, and no concerns were raised.

### 1.5.1 Challenges in trial design

Despite recent advances in non-invasive markers of liver injury (e.g. transient elastography, serum fibrosis markers), liver biopsy remains the recommended method for assessment of disease activity for phase II/III trials (33). Liver biopsy is not without its limitations (such as sampling error, invasive nature and patient reluctance for repeat sampling (47)), but until the accuracy of serial measurements of non-invasive markers have been formally validated, it will be required for trials in NASH. The LEAN trial has attempted to minimise these limitations. First, liver biopsies (<6 months of screening) performed for routine NHS diagnostic purposes were incorporated into the eligibility criteria and utilised as the baseline comparator, rather than performing two biopsies for the sole purposes of the trial. This approach is widely accepted in trials of NASH. Second, all of the liver biopsies (baseline, primary end-point) underwent a blinded central review by two independent expert liver histopathologists (RB, SGH) at the one site, ensuring that only patients with 'definite' NASH were recruited to the trial and reducing intra/inter-assessor variability, which has previously been reported between trial sites (48).

1  
2  
3 In 2011, Sanyal and colleagues (update from AASLD research workshop, 2009)  
4  
5 published expert guidance on clinical trial design in patients with NASH (33). Even  
6  
7 though the LEAN trial design preceded this workshop, the definition of NASH and the  
8  
9 outcome measures were in keeping with their recommendations. Patients with  
10  
11 NASH have a higher risk of liver-related mortality than those with simple hepatic  
12  
13 steatosis (+/- mild inflammation) (49, 50). Due to the long time-span of NASH  
14  
15 progression (i.e. 10-20 years) to end-stage liver failure/death it is impractical to  
16  
17 perform therapeutic trials with mortality as the primary outcome measure.  
18  
19 Therefore, we elected to use disappearance of NASH with no worsening of fibrosis as  
20  
21 'surrogate' primary end-point in LEAN. With this in mind, 48-weeks treatment  
22  
23 duration was selected, rather than 2-5 years, which would be required if we were  
24  
25 aiming to demonstrate significant improvements in fibrosis. NAS has been  
26  
27 incorporated as a secondary outcome measure (inc. the individual components of  
28  
29 NAS) to represent disease activity (31), rather than as the primary outcome as  
30  
31 previously reported (48, 51). NAS alone was not originally designed to infer absence  
32  
33 or presence of NASH (52), which we deemed a more meaningful clinical outcome.  
34  
35  
36  
37  
38  
39  
40  
41  
42

43 We elected to recruit patients with and without type 2 diabetes to enhance  
44  
45 recruitment rates and broaden the safety data in liraglutide in NASH, but under the  
46  
47 provision that patients with diabetes must have moderate glycaemic control (HbA1c  
48  
49 <9.0%) on diet +/- oral hypoglycaemic medications (with the exception of TZDs and  
50  
51 other potential confounders i.e. GLP-1 based therapy) prior to trial entry. In the  
52  
53 knowledge that diabetes is a potential confounding factor, randomisation was  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 programmed to stratify for diabetes to ensure equal numbers in each treatment  
4  
5 arm.  
6  
7

8  
9  
10 Efficient recruitment for clinical trials in NASH remains a challenge, mainly due to the  
11  
12 requirement for liver biopsy, which has been compounded by the recent uptake of  
13  
14 non-invasive markers (e.g. transient elastography) in the UK resulting in a decline in  
15  
16 liver biopsy requests in some recruiting centres (37).  
17  
18  
19

### 20 21 **1.5.2 Safety profile of liraglutide** 22 23

24  
25  
26 Prior to the start of the LEAN trial, the summary of product characteristics (SmPc) for  
27  
28 liraglutide (Victoza®) stated special warnings and precautions for use in  
29  
30 moderate/severe renal impairment, moderate/severe congestive heart failure  
31  
32 (NHYA class III/IV), pre-existing thyroid disease and in patients at risk of  
33  
34 pancreatitis/pancreatic carcinoma (53). In turn, the eligibility criteria (**Table 1**)  
35  
36 reflected these warnings by excluding patients with or at risk of such. In particular,  
37  
38 based on the pre-clinical incidence of thyroid C-cell tumours in rodent models and  
39  
40 the manufacturers 'black box' warning in humans (53), all patients with a personal  
41  
42 history/family history of thyroid carcinoma, multiple endocrine neoplasia syndrome  
43  
44 type 2 and/or abnormal thyroid examination (goiter, nodules) were excluded from  
45  
46 the trial. In addition, serum calcitonin, TFTs and clinical thyroid examination were  
47  
48 monitored throughout the trial as a precautionary measure.  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 In keeping with both US Food and Drug Administration (FDA) (54) and European  
4  
5 Medicines Agency (EMA) (55) recommendations, all patients in LEAN were given  
6  
7 written/verbal advise about the risks and carefully monitored for signs and  
8  
9 symptoms indicative of pancreatitis. In Marsh 2013, a small study (n=8) by Butler et  
10  
11 al reported pancreatic cellular changes, consistent with pancreatic duct metaplasia,  
12  
13 in organ donors who had received GLP-1 therapy for diabetes prior to death (56). In  
14  
15 response in July 2013, the EMA's committee of Medicinal Products for Human Use  
16  
17 (CHMP) critically appraised the study and all other non-clinical/clinical data available,  
18  
19 and concluded that the current evidence did not confirm an increased risk of  
20  
21 pancreatic adverse events with GLP-1 based therapies (57). Subsequently, the  
22  
23 current safety measures adopted by the LEAN trial will continue until further  
24  
25 information is made available.  
26  
27  
28  
29  
30  
31

### 32 **1.5.3 Summary**

33  
34  
35  
36  
37 To the best of our knowledge, the LEAN trial is the first multi-centre, double-blinded,  
38  
39 placebo-controlled RCT designed to investigate whether the long-acting GLP-1  
40  
41 analogue, liraglutide, is safe and improves liver histology in overweight patients with  
42  
43 NASH. The enrolment of the required sample size was completed in May 2013 and  
44  
45 the final results are expected by the end of 2014. The full LEAN protocol (version 7.0)  
46  
47 can be obtained from the NIHR liver biomedical research unit and CRCTU at the  
48  
49 University of Birmingham ([LEAN@trials.bham.ac.uk](mailto:LEAN@trials.bham.ac.uk)).  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

**Generic Exclusion criteria:**

1. Refusal or lacks capacity to give informed consent to participate in the trial
2. Participation in any clinical trial of an investigational therapy or agent within 3 months of randomisation
3. Patient (or carer) deemed not competent at using the correct site and technique for subcutaneous injection of the trial treatment (containing dummy drug on practice)
4. NAFLD Activity Score (NAS) < 3 on liver biopsy
5. Child's B or C cirrhosis
6. Past medical history of multiple drug allergies (defined as anaphylactoid drug reactions in >2 drug groups)
7. Presence of any acute/chronic infections or illness that at the discretion of the chief investigator might compromise the patient's health and safety in the trial
8. Pregnancy or breastfeeding
9. Women, of child-bearing age, who are not willing to practise effective contraception (i.e. barrier, oral contraceptive pill, impenon or past medical history of hysterectomy) for the 48 week duration of the trial and for one-month after the last administration of the drug.
10. Men, sexually active with women of child-bearing age, who are not willing to practise effective contraception for the 48 week duration of the trial and for one-month after the last administration of the drug.
11. Liver disease of other aetiologies (i.e. drug-induced, viral hepatitis, autoimmune hepatitis, PBC, PSC, haemochromatosis, A1AT deficiency, Wilsons disease)
12. Past medical/surgery history of; Gastric bypass surgery, orthotopic liver transplant (OLT) or listed for OLT, hepatocellular, pancreatic, thyroid carcinoma, multiple endocrine neoplasia syndrome type 2 (MEN 2), acute or chronic pancreatitis, and total parenteral nutrition within 6 months of randomisation.
13. Diagnosis of malignancy within the last 3 years (with the exception of treated skin malignancies)
14. Hepatocellular Carcinoma: dysplastic or intermediate nodules to be excluded. Borderline cases to be discussed at Birmingham's tertiary hepato-biliary multidisciplinary team (MDT) meeting. Regenerative and other nodules to be included at the discretion of the chief investigator and the MDT.
15. Family history of medullary thyroid carcinoma
16. Clinical evidence of decompensated chronic liver disease: radiological or clinical evidence of ascites, current or previous hepatic encephalopathy and evidence of portal hypertensive haemorrhage or varices on endoscopy
17. Abnormal clinical examination of thyroid (i.e. unexplained goitre or palpable nodules)
18. ALT or AST > 10 x upper limit of normal
19. Average alcohol consumption/week male >21 (approx. 210g), female >14 units (approx. 140g) within the last 5 years.
20. >5% weight loss since the diagnostic liver biopsy was obtained.
21. Recent (within 3 months of the diagnostic liver biopsy or screening visit) or significant change (as judged by the chief investigator) in dose of the following drugs: Inducers of hepatic steatosis (steroids (oral/intravenous), methotrexate, amiodarone), orlistat and/or multi-vitamins/vitamin E (containing >200% recommended daily amount; >30mg/day)
22. Known positivity for antibody to Human Immunodeficiency virus (HIV)
23. Serum creatinine >150 µmol/L or currently being treated with renal replacement therapy (i.e. Haemodialysis or Peritoneal Dialysis)

**Specific exclusion criteria for subjects with T2D:**

1. Current or previous insulin therapy, with exception of previous short-term insulin treatment in connection with intercurrent illness is allowed (≥ 3 months prior to screening), at the discretion of the chief investigator.
2. Subjects receiving thiazolidinediones (TZDs), dipeptidyl peptidase (DPP) IV inhibitors and other GLP-1 based therapies (i.e. exenatide)
3. HbA1c ≥ 9.0%
4. Recurrent major hypoglycaemia or hypoglycaemic unawareness as judged by the chief investigator

**Table 1: Exclusion criteria for LEAN trial**

	Screening		Treatment (TD, treatment day)					Follow-up
	Visit 1 (Max -14 days to TD1)	Visit 2 (1 day prior to TD1)	Visit 3 (TD 28)	Visit 4 (TD 84)	Visit 5 (TD 168)	Visit 6 (TD 252)	Visit 7 (1 Day + TD 336/ End of Treatment [EOT])	Visit 8 (12 weeks after EOT)

**Table 2. Trial schedule of data collection**

**Figure legends:**

**Figure 1: Schematic of LEAN trial design.**

Eligible participants are randomly assigned to 48 weeks treatment of once-daily (OD) subcutaneous injections (SC) of either 1.8mg liraglutide or placebo-control. Both the trial investigators and the participants are blinded to drug allocation.

**Figure 2: Histological inclusion criteria for LEAN trial.** Liver biopsy sections (actual magnification 400X). **[A – B] 'Uncertain' NASH - not eligible for LEAN:** **[A]** H&E stain highlights fat, inflammation and some pale cells, however **[B]** ubiquitin immunohistochemistry does not identify any Mallory Denk bodies (no confirmed ballooning). **[C – D] 'Uncertain' NASH - eligible for LEAN:** **[C]** H&E stain highlights fat, inflammation and pale cells, but with no obvious Mallory Denk bodies. However, ubiquitin staining **[D]** is positive (confirming ballooned hepatocytes). **[E – F] 'Definite' NASH - eligible for LEAN:** Both H&E and ubiquitin staining highlight fat, lobular inflammation and widespread ballooned hepatocytes. Black arrows highlight Mallory Denk bodies.

**Table 1: LEAN trial Exclusion criteria**

Patients who met any of the criteria (*listed* above) at the screening visit were excluded from trial participation

**Table 2: Data collection schedule**

**[1]** Clinical assessment: complete history/examination (visit 1), focussed history/examination (visits 2-8). **[2]** Vital signs: HR, BP, weight, Height, waist:hip circumference, body temperature, SaO<sub>2</sub>, RR. **[3]** Standard fasting blood tests: FBC, U+E, LFTs, INR, TFTs, glucose and HbA1c (*except* visit 3). **[4]** Screening blood tests: HBsAg, HCV Ab, AMA/ASA/immunoglobulins, Ferritin/Transferrin saturation, Caeruloplasmin, α1AT, AFP. **[5]** FibroMAX panel (FibroTest, SteatoTest, NashTest), ELF tests and transient elastography (Fibroscan; optional depending on availability). **[6]** Optional metabolic sub-study: 2-step hyperinsulinaemic euglycaemic clamp with stable isotope studies and adipose microdialysis. **[7]** Questionnaires: AUDIT, Block Brief 2000 FFQ, HR-QOL (SF-36v2). **[8]** Diagnostic liver biopsy performed as part of standard NHS care ≤6 months of screening visit 1. Two independent liver histopathologists will review the liver biopsy to assess whether the patients meets the histological inclusion criteria. Adverse Events/bloods and Clinical Events will be monitored continuously until completion of follow up and 30 days after. Calcitonin

1  
2  
3 and AFP levels will be measured at visits 1, 5, 7 and 8. [10] If the study patient meets  
4 the eligibility criteria, he/she will be randomised at visit 2 to receive liraglutide  
5 (Victoza®) or placebo. The allocated blinded study treatment will be dispensed at  
6 visit.  
7

8  
9  
10 **Supplementary Table 1: Trial proforma for the histopathological assessment of pre-  
11 and post-treatment liver biopsies.**

12 Two independent liver histopathologists will perform the histological assessments on  
13 the pre and post treatment liver biopsies. \*In the event that one histopathologist  
14 reports the diagnosis of NASH as 'uncertain,' then a joint review will take place to  
15 determine if the participant is eligibly for randomization. If both histopathologists  
16 regard the case as "uncertain", this is classed as "no" for eligibility purposes.  
17

18  
19  
20 **Supplementary Figure 1: Recruitment rate for LEAN trial**

21 In total 52 patients were recruited over a period of 32 months  
22  
23

24  
25 **Author contributions:**

26  
27 MJA, SG, JWT, and PNN (Chief Investigator) had the original concept of the LEAN  
28 trial. MJA, SG, JWT, and PNN designed the LEAN trial and wrote/reviewed all  
29 protocol versions. RB and SGH designed the proforma used for recording  
30 histopathological findings and carried out the central histopathology review of all  
31 pre- and post-treatment liver biopsies. MJA and DB (senior trials coordinator)  
32 submitted all REC, MHRA and local R&D applications. MJA, PNN, PG and DS devised  
33 the statistical plan. PG prepared the bi-annual DMC reports. MJA, DB, DH, and KG  
34 wrote/designed the patient information sheets, external trial information and  
35 patient CRFs. MJA wrote the manuscript and all authors reviewed the final version.

### 31 32 33 **Acknowledgements:**

34  
35 The LEAN trial would like to thank the Data Management Committee (DMC)  
36  
37 consisting of Professor Peter Hayes (DMC Chair; independent Liver expert), Sarah  
38  
39 Brown (Independent Senior Statistician) and Dr Jude Oben (Independent Liver  
40  
41 expert) for their time and input. The LEAN trial is funded by Wellcome Trust (Clinical  
42  
43 Research Fellowship awarded to MJA), Novo Nordisk Ltd (educational grant, free  
44  
45 supply of trial drugs) and the NIHR Liver BRU.  
46  
47  
48  
49  
50

### 51 52 **Conflict of Interests:**

53  
54 PNN and MJA have received an educational grant and free trial drug supply from  
55  
56 Novo Nordisk for conduct of the LEAN trial of liraglutide in NASH. PNN has received  
57  
58  
59  
60

1  
2 honoraria for lectures given on behalf of Novo Nordisk. SCLG has served on advisory  
3  
4 boards for Novo Nordisk, Eli Lilly, Sanofi Aventis and Takeda, and has received  
5  
6 honoraria for lectures given on behalf of Novo Nordisk, Eli Lilly, Sanofi Aventis,  
7  
8 Takeda and GSK. JWT, DB, DH, KG, DS and PG have no conflict of interests to declare.  
9

<b>Quality of analysed liver biopsy</b>	Number of complete portal tracts ___ Length of liver specimen (mm) _____
<b>NAFLD Activity Score (NAS), (Kleiner et al [31])</b>	<b>Composite score ( _/8)</b>
Steatosis, ( _/3)	0=<5%; 1=5-33%; 2=>33-66%; 3=>66%
Lobular inflammation, ( _/3)	0=No foci; 1=<2 foci/200x; 2=2-4 foci/200x; 3=>4 foci/ 200x
Hepatocyte Ballooning, ( _/2)	0=None; 1=few ballooned cells; 2=many cells/prominent ballooning
<b>Portal tract changes</b>	
Portal inflammation ( _/4) (Ishak et al [34])	0=None; 1=Mild, some or all portal areas; 2=Moderate, some or all portal areas; 3=Moderate/marked, all portal areas; 4=Marked, all portal areas.
Interface hepatitis ( _/4) (Ishak et al,[34])	0=Absent; 1=Mild (focal, few portal areas); 2=Mild/moderate (focal, most portal areas) 3=Moderate (continuous around <50% of tracts or septa); 4=Severe (continuous around >50% of tracts or septa)
Ductular reaction ( _/3)	1= focal in <50% of portal tracts 2= focal in >50% of portal tracts <u>or</u> prominent in <50% of portal tracts. 3=prominent in >50% of portal tracts.
<b>Kleiner Fibrosis Score (F0-F4) (Kleiner at al, [31])</b>	<i>(select one from the list)</i>
F0	No fibrosis
F1 [1A-1C]	Perisinusoidal OR Periportal [1A=mild, zone 3, perisinusoidal; 1B=moderate, zone 3, perisinusoidal; 1C=portal/periportal]
F2	Perisinusoidal and Portal/periportal
F3	Bridging fibrosis
F4	Cirrhosis
<b>Modified version of Ishak score for fibrosis [34]</b>	<i>(Select one from the list)</i>
0	No fibrosis
1	Zonal fibrosis involving a minority of zone 3 areas and/or portal tracts [specify whether pericellular and/or periportal]
2	Zonal fibrosis involving a majority of zone 3 areas and/or portal tracts [specify whether pericellular and/or periportal]
3	Bridging fibrosis-occasional foci [specify where central-central or central-portal or portal-portal]
4	Bridging fibrosis-widespread [specify where central-central or central-portal or portal-portal]
5	Bridging fibrosis-widespread, with occasional nodule (incomplete cirrhosis)
6	Cirrhosis – probable

Supplementary table 1

## CONSORT 2010 checklist of information to include when reporting a randomised trial\*

Section/Topic	Item No	Checklist item	Reported on page No
<b>Title and abstract</b>			
	1a	Identification as a randomised trial in the title	1
	1b	Structured summary of trial design, methods, results, and conclusions (for specific guidance see CONSORT for abstracts)	3
<b>Introduction</b>			
Background and objectives	2a	Scientific background and explanation of rationale	5-6
	2b	Specific objectives or hypotheses	5-6
<b>Methods</b>			
Trial design	3a	Description of trial design (such as parallel, factorial) including allocation ratio	8
	3b	Important changes to methods after trial commencement (such as eligibility criteria), with reasons	8-21
Participants	4a	Eligibility criteria for participants	23-25
	4b	Settings and locations where the data were collected	8-25
Interventions	5	The interventions for each group with sufficient details to allow replication, including how and when they were actually administered	9-10
Outcomes	6a	Completely defined pre-specified primary and secondary outcome measures, including how and when they were assessed	12-13
	6b	Any changes to trial outcomes after the trial commenced, with reasons	NA
Sample size	7a	How sample size was determined	18-19
	7b	When applicable, explanation of any interim analyses and stopping guidelines	25-27, 29-30
<b>Randomisation:</b>			
Sequence generation	8a	Method used to generate the random allocation sequence	25
	8b	Type of randomisation; details of any restriction (such as blocking and block size)	25
Allocation concealment mechanism	9	Mechanism used to implement the random allocation sequence (such as sequentially numbered containers), describing any steps taken to conceal the sequence until interventions were assigned	25
Implementation	10	Who generated the random allocation sequence, who enrolled participants, and who assigned participants to interventions	20-28
Blinding	11a	If done, who was blinded after assignment to interventions (for example, participants, care providers, those	13 onwards

1			
2		assessing outcomes) and how	
3			
4		11b If relevant, description of the similarity of interventions	9-10
5	Statistical methods	12a Statistical methods used to compare groups for primary and secondary outcomes	19-21
6		12b Methods for additional analyses, such as subgroup analyses and adjusted analyses	19-21
7			
8	<b>Results</b>		
9	Participant flow (a	13a For each group, the numbers of participants who were randomly assigned, received intended treatment, and	NA, protocol
10	diagram is strongly	were analysed for the primary outcome	only
11	recommended)	13b For each group, losses and exclusions after randomisation, together with reasons	“”
12	Recruitment	14a Dates defining the periods of recruitment and follow-up	“”
13		14b Why the trial ended or was stopped	“”
14			
15	Baseline data	15 A table showing baseline demographic and clinical characteristics for each group	“”
16	Numbers analysed	16 For each group, number of participants (denominator) included in each analysis and whether the analysis was	“”
17		by original assigned groups	
18			
19	Outcomes and	17a For each primary and secondary outcome, results for each group, and the estimated effect size and its	“”
20	estimation	precision (such as 95% confidence interval)	
21		17b For binary outcomes, presentation of both absolute and relative effect sizes is recommended	“”
22	Ancillary analyses	18 Results of any other analyses performed, including subgroup analyses and adjusted analyses, distinguishing	“”
23		pre-specified from exploratory	
24			
25	Harms	19 All important harms or unintended effects in each group (for specific guidance see CONSORT for harms)	“”
26			
27	<b>Discussion</b>		
28	Limitations	20 Trial limitations, addressing sources of potential bias, imprecision, and, if relevant, multiplicity of analyses	“”
29	Generalisability	21 Generalisability (external validity, applicability) of the trial findings	“”
30	Interpretation	22 Interpretation consistent with results, balancing benefits and harms, and considering other relevant evidence	“”
31			
32	<b>Other information</b>		
33	Registration	23 Registration number and name of trial registry	3
34	Protocol	24 Where the full trial protocol can be accessed, if available	36
35	Funding	25 Sources of funding and other support (such as supply of drugs), role of funders	31
36			

37

38 \*We strongly recommend reading this statement in conjunction with the CONSORT 2010 Explanation and Elaboration for important clarifications on all the items. If relevant, we also

39 recommend reading CONSORT extensions for cluster randomised trials, non-inferiority and equivalence trials, non-pharmacological treatments, herbal interventions, and pragmatic trials.

40 Additional extensions are forthcoming: for those and for up to date references relevant to this checklist, see [www.consort-statement.org](http://www.consort-statement.org).
