Models were adjusted for age, race, gender, smoking, diabetes, hypercholesterolemia, systolic blood pressure, antihypertensive medications, physical activity, heart rate and LV mass index. Variance inflation factor was < 2 in all models. See Table 1 for abbreviations.

**Supplemental Figure S1.**

Mediators are conceptualized as being within the causal pathway of the predictor and the outcome of interest (**A** & **B** above: visceral adiposity affects triglycerides, SHBG, adiponectin and leptin and they affect diastolic function). If one ignores the mediators (in this example, triglycerides, SHBG, adiponectin and leptin), one will observe a relationship between the predictor, visceral adiposity, and the outcome variable, diastolic function (**C**). Adjusting for mediators results in an attenuation or elimination of the relationship between the predictor and the outcome variable (**C\***). Although such findings lend support to a hypothesis, the findings do not confirm mediation, either partial or complete.
