

Supplementary Figure 1. Demonstration of non-specific staining with antiIgM secondary antibody in pancreatic sections of 10 wks old NOD mice. A: DAPI nuclear stain. B: Islets from 10 wks NOD mice were heavily infiltrated by mononuclear cells as evident from anti-CD3. C: Staining with secondary anti-IgG antibody (no primary anti-insulin antibody). D: Staining with secondary anti-IgM antibody (no primary IC2 antibody). E: Co-localization of anti-IgM staining with mononuclear cell infiltrate indicating the presence of IgM specificities in these invading cells.
