HRFI = High residual feed intake , LRFI = Low residual feed intake, HF = High forage, LF = Low forage

<sup>1</sup>Genbank accession number of closest taxon

2 **Supplementary Figures:**

3

4 **Figure S1.** Phylogenetic placement of archaeal clones derived from 16S rRNA gene

5 evolutionary distances produced by using a maximum likelihood approach in PhyML.

6 The tree was created using interactive tree of life (ITOL) <http://itol.embl.de/> (33) .The

7 tree was bootstrap-resampled 1000 times and the bootstrap resampling values for 16S

8 rRNA gene sequences (expressed as percentages) are indicated at the nodes.

9 Clostridium sp. (Agric0) was used as the out-group for rooting the tree. The bar

10 represents a sequence divergence of 10%. The Genbank accession numbers for

11 nucleotide sequences are given in parentheses.Higher Taxonomic groupings are

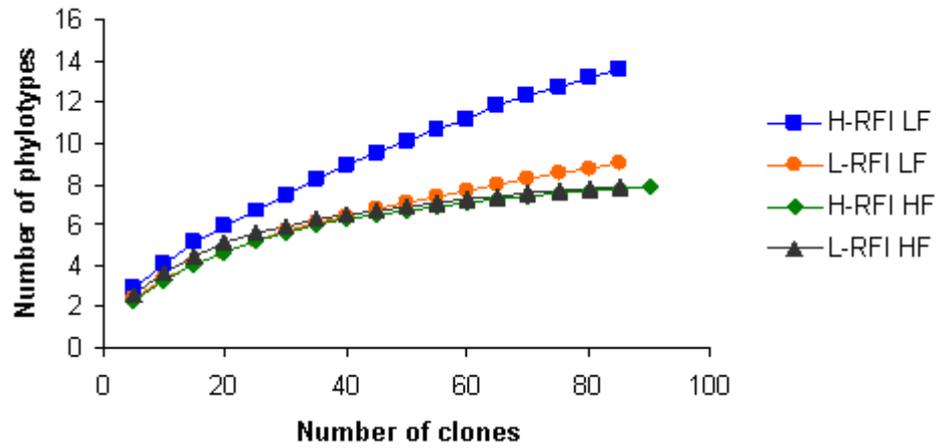

12 indicated as follows: 1, *Methanococcales*; 2, *Methanobacteriales*; 3, uncultured

13 archaea; 4, *Thermoplasmatales*; 5, *Methanomicrobiales*; 6, *Methanosarcinales*; 7,

14 *Methanopyrales*. Piecharts at internal nodes represent the percentage of clones from

15 HRFI-HF, LRFI-HF, HRFI-LF and LRFI-LF libraries from each phylotype.

16

17

18 **Figure S2.** Rarefaction curves for methanogen 16S rRNA gene sequences obtained  
 19 from HRFI-HF, LRFI-HF, HRFI-LF and LRFI-LF clone libraries at the 97%  
 20 sequence similarity level.

34 **Figure S3.** Rarefaction curves for archaeal 16S rRNA gene sequences obtained by  
 35 tag-encoded FLX-Titanium amplicon sequencing of bovine rumen fluid obtained from  
 36 (A) animals divergently selected for phenotypic RFI and (B) while offered a HF and  
 37 LF diet respectively. The curves indicate the observed number of operational  
 38 taxonomic units (OTUs) at 98% similarity. The curves generated with the sequences  
 39 from the high residual feed intake (HRFI) and low residual feed intake (LRFI)  
 40 phenotypes are marked by black and grey respectively. The curves generated with

41 sequences from animals while maintained on a high forage (HF) and low forage (LF)  
42 diet are marked by blue and red, respectively.

74 **Figure S5.** Phylogeny of the V3 region of archaeal 16S rRNA type sequences from  
 75 the Ribosomal Database Project (29). The phylogenetic position of the OTUs  
 76 discovered from pyrosequencing are indicated. The bars represent the abundance of  
 77 each of the OTU in HRFI samples (in green) and LRFI samples (in blue). Dots at  
 78 internal branches indicate bootstrap support greater than 80%. The methanobacteriales  
 79 clade is shown in Figure 2.

80

81

82

83 **Supplementary file S1**

84 **16S rDNA clone library construction and sequencing**

85 Individual PCR amplicons were pooled by mixing 4 µl of each sample from;  
86 HRFI animals (n = 14) on the HF diet (library 1, HRFI-HF); LRFI animals (n = 14) on  
87 the HF diet (library 2, LRFI-HF); HRFI animals (n = 14) on the LF diet (library 3,  
88 HRFI-LF) and LRFI animals (n=14) on the LF diet (library 4, LRFI-LF) for library  
89 construction. Methanogen specific 16S rRNA gene clone libraries were constructed  
90 by cloning pooled PCR products into TOP10 vectors (TOPO TA cloning kit;  
91 Invitrogen, Carlsbad, CA, USA) by chemical transformation. Colonies with insertion  
92 from each of the four libraries (libraries 1, 2 3 and 4) were randomly selected on X-  
93 Gal (Sigma-Aldrich Ireland Ltd. Dublin, Ireland) medium, and the plasmid DNA was  
94 extracted using a QIAprep<sup>®</sup> Spin miniprep Kit (Qiagen Ltd, Crawley, UK). All  
95 extracted plasmid DNA was diluted to a concentration of 100 ng µl<sup>-1</sup> and 20 µl of  
96 diluted DNA was transferred individually to a well of a 96-well qPCR plate (Applied  
97 Biosystems, Warrington, UK). From libraries 1, 2, 3 and 4; 94, 89, 89 and 87 clones  
98 were randomly selected, respectively, and subjected to sequence analysis by the  
99 dideoxy-chain termination method with an ABI 3730 XL sequencer using the  
100 sequencing service provided by Macrogen (Seoul, Korea) with both M13 forward  
101 (CGCCAGGGTTTTCCCAGTCACGAC) and M13 reverse  
102 (TTCACACAGGAAACAGCTATGAC) primers according to the manufacturer's  
103 instructions.

106

107

108

109 **Supplementary file S2**

110 **Clone library analysis**

111 All DNA sequence reads of the partial 16S rRNA gene sequences from  
112 methanogenic clone libraries were trimmed manually. Sequences were searched using  
113 the basic local alignment and search tool from the National centre for Biotechnology  
114 Information (BLAST: <http://blast.ncbi.nlm.nih.gov/Blast.cgi>) for comparison with  
115 sequences available in the GenBank database. Sequences were aligned using  
116 MUSCLE (22), manually edited and clustered for classification by using the program  
117 CD-HIT (23). The number of clusters found at percentage identity cut-offs from 90 %  
118 to 100 % were calculated. These values were plotted and used to determine an  
119 optimum cut-off for this dataset of 97 %. This value represented an appropriate  
120 balance between the number of clusters identified and the number of sequences in  
121 each cluster (Figure S1). A phylogenetic tree was constructed from the alignments  
122 and a bootstrap analysis of the tree was carried out with 1000 repetitions using  
123 maximum likelihood approach in PhyML (24). gamma distribution representing site-  
124 rate heterogeneity with an estimated alpha parameter, summarised into four site-rate  
125 categories were the settings employed. The model of evaluation used was LG as  
126 implemented in PhyML. Rarefaction analysis was performed to determine if the  
127 number of methanogenic clones screened in this study was sufficient for accurate  
128 estimation of the diversity in each of the four clone libraries. Chao analyses, Shannon  
129 diversity index and Simpson's diversity index were calculated to assess the richness  
130 and diversity of our clone libraries. Clone library evenness was calculated according  
131 to the equation  $J' = H'/H'_{\max}$ , where  $H'$  is the Shannon diversity index and  $H'_{\max}$  is the  
132 logarithm of the number of species (61). Community coverage was calculated  
133 according to the equation:  $C = 1 - (n/N)$ , where  $n$  is the number of phylotypes

134 represented by one clone and  $N$  is the total number of clones examined in each library  
135 (34). The Shannon diversity index is a non parametric diversity index that  
136 incorporates both richness ( $S$ , total number of OTUs) and evenness ( $E$ , relative  
137 abundance of OTUs). The Chao1 index is a nonparametric estimator of the minimum  
138 richness within the studied clone library, thus estimating the number of predicted  
139 phylotypes while the Simpson's index of diversity calculates the probability that two  
140 individuals selected from the same sample will belong to the same taxonomic  
141 category. Rarefaction curves were produced by using an analytical approximation  
142 algorithm utilising the freeware software package: Analytical Rarefaction v1.3  
143 (<http://www.uga.edu/strata/software/Software.html>). Chao I, Shannon index and  
144 Simpson index were calculated using the freeware software package EstimateS v8.2.0  
145 (<http://viceroy.eeb.uconn.edu/EstimateS>). The nucleotide sequences reported herein  
146 have been deposited in the Genbank database under accession numbers JQ952744 to  
147 JQ952761 with the prefix "AGRIC".
