

Supplementary Information

Resonance Assignment of the NMR Spectra of Disordered Proteins Using a Multi-Objective Non-Dominated Sorting Genetic Algorithm

Yu Yang, Keith J. Fritzsching, and Mei Hong*

Department of Chemistry, Iowa State University, Ames, Iowa 50011

Mutation and crossover operators in the modified NSGA-II and combination NSGA-II/MC algorithms

The assignment result in our program is stored in an $N_{\text{res}} \times M$ matrix, where N_{res} is the number of residues in the sequence and M is the number of spectra. Name the matrix as \mathbf{p} , and $\mathbf{p}(i, j)$ is the number of the peak in the j^{th} spectrum that is assigned to the i^{th} residue in the sequence. If $\mathbf{p}(i, j) = 0$, then it means the i^{th} residue contributes to none of the cross peaks in the j^{th} spectrum.

The crossover operator, which is also called “recombination”, uses two parents to generate two children. For convenience, the two parents are represented by $\mathbf{p}_1(i, j)$ and $\mathbf{p}_2(i, j)$, where $i = 1, 2, \dots, N_{\text{res}}$; $j = 1, 2, \dots, M$. Randomly choose the k^{th} residue in the sequence, and the q^{th} spectrum, exchange the assignments of the two parents, i.e. $\mathbf{p}_1(k, q)$ and $\mathbf{p}_2(k, q)$ but keep other residues' assignment the same, then two new children \mathbf{c}_1 and \mathbf{c}_2 are obtained. In doing so care must be taken that the maximum degeneracies of the newly assigned peaks are not exceeded.

The mutation operator uses one parent to generate one child. In our program, three mutation operators are designed. The first one is called simple mutation: randomly choose a spectrum index q and a residue k ; change the assigned peak number $\mathbf{p}(k, q)$ to another peak or 0. The second operator is called exchange mutation: randomly choose a spectrum index q , and two residues k_1 and k_2 ($k_1 \neq k_2$); exchange the two assignments $\mathbf{p}(k_1, q)$ and $\mathbf{p}(k_2, q)$. The third operator is called multi-exchange mutation: randomly choose two residues k_1 and k_2 ; exchange the assignments of the k_1^{th} residue and the k_2^{th} residue in each spectrum. While changing the assignment of a residue, all normal constraints must be satisfied. This means that the possible residue types of the assigned peak given in the peak list should include the residue that the peak is assigned to, and the maximum degeneracy of the assigned peak must not be exceed. These three mutation operators are used for making multiple changes to the previous solution in a single step. Proper design of the operator can prevent the algorithm from being trapped in a local optimum. The users can also design their own operators to make the algorithm work more effectively.

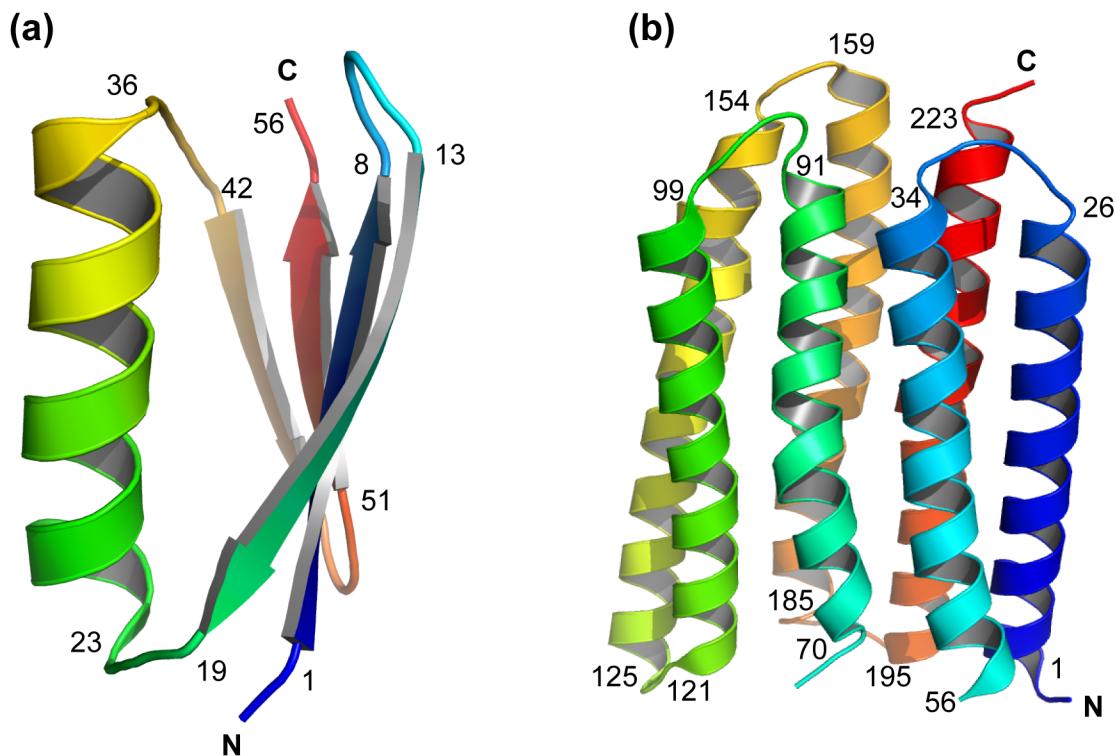

Figure S1. Cartoon representations of (a) GB1 (PDB: 2QMT) and (b) sensory rhodopsin (PDB: 1XIO). Key residue numbers are indicated to denote the positions of the deleted residues in the input peak lists.

Table S1. GB1 peak lists with 20% consecutive deletion.
