

Supplementary Fig. 1. Effects of the highest dose of WIN on MG63 cell cycle distribution.

Flow cytometric analysis was carried out on propidium iodide stained cells treated for 24 h or 48 h with 20 μM WIN in the presence or absence of 100 μM z-VAD. The percentage of cells in each phase of the cell cycle was calculated using Expo32 software. The plots are representative of three independent experiments.
