

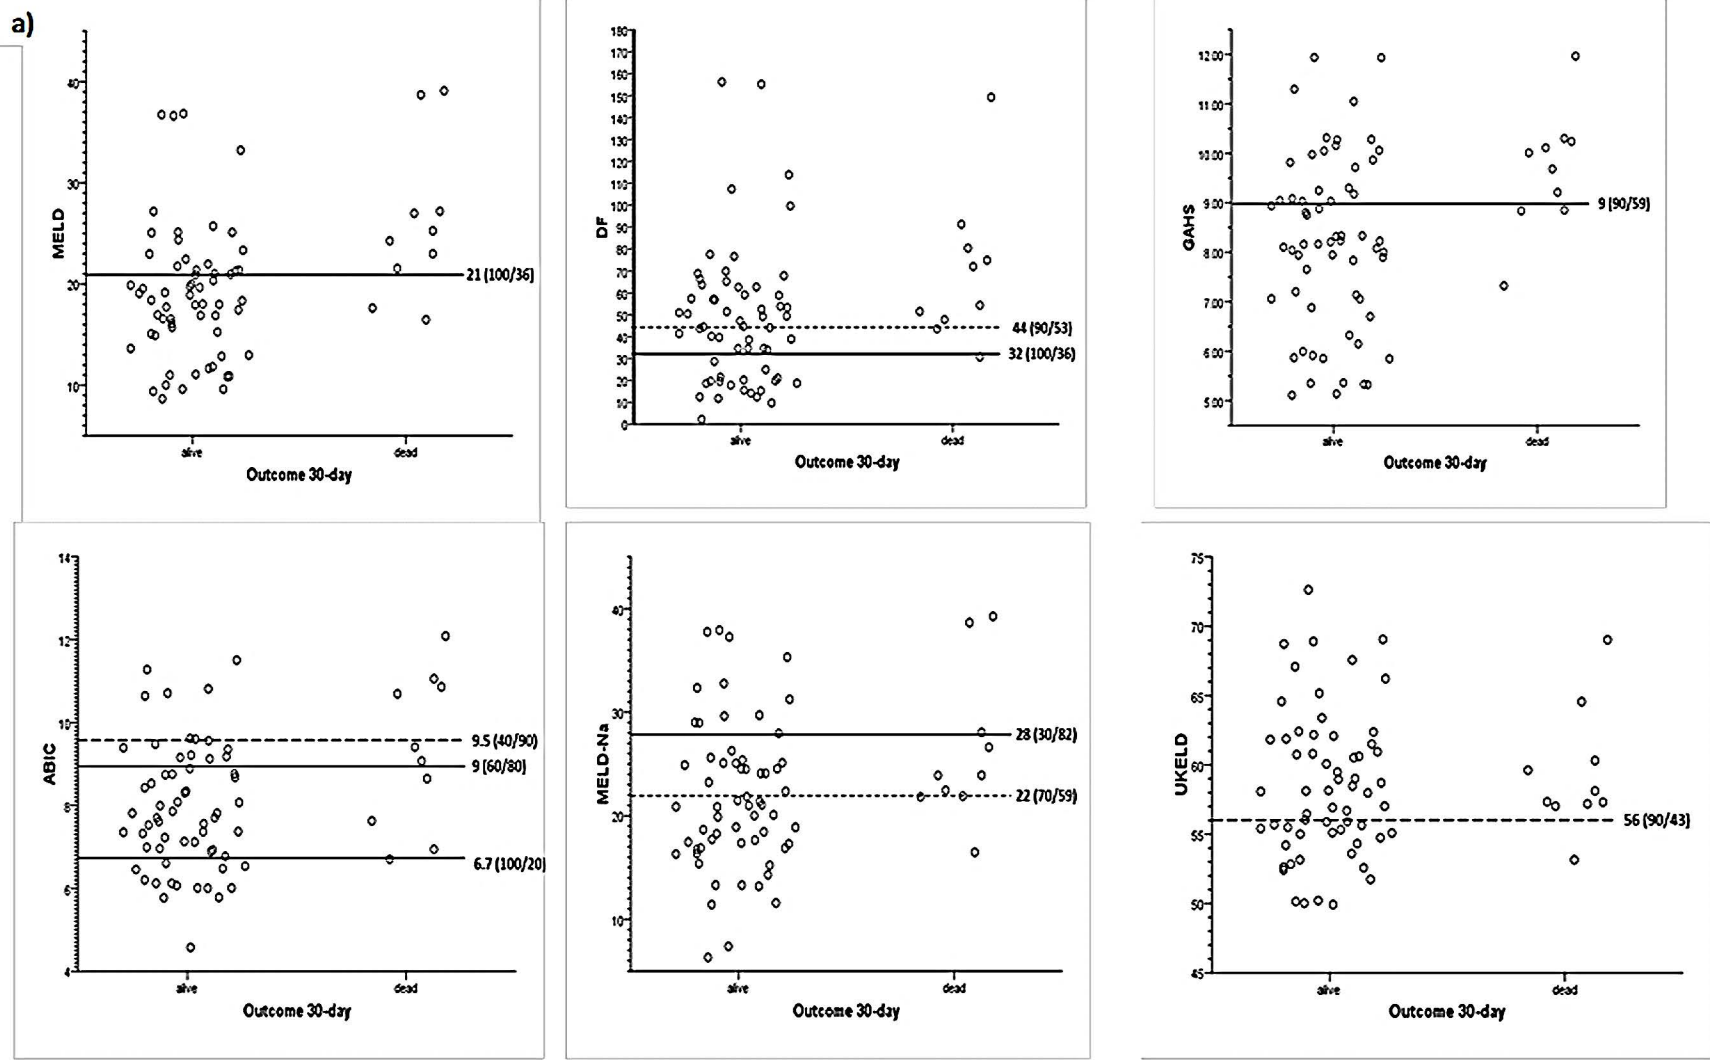

Figure S1. Scatter plots of admission score values for prognostic scores in alcoholic hepatitis correlated with 30- (a) and 90-day (b) mortality. Solid lines represent originally published cut-offs. Dotted lines represent optimal cut-points as determined by the receiver operating curve coordinates. For ABIC optimal low (yielding max sensitivity) and high (yielding max specificity) cut-off values were determined, similarly to the original description of the model ¹⁴. Optimal MELD, GASH and low ABIC cut-offs within our cohort fitted those originally published ^{14, 16, 20}. Sensitivity/specificity (%) for each cut-off value are shown in parentheses.
