Abstract

Objectives: Develop predictive models using an administrative health care database that provide information for Patient Centered Medical Homes to proactively identify patients at risk of hospitalization for conditions that may be impacted through improved patient care.

Design: Retrospective health care utilization analysis with multivariate logistic regression models.

Data: A population-based longitudinal database of residents served by the Emilia-Romagna, Italy health service in the years 2004-2012 including demographic information and utilization of health services by 3,726,380 people age ≥ 18 years.

Outcome measures: Models designed to predict risk of hospitalization or death for problems that are potentially avoidable were developed and evaluated using the area under the receiver operating curve C-statistic, in terms of their sensitivity, specificity, and positive predictive value, and for calibration to assess performance across levels of predicted risk.

Results: Among the 3,726,380 adult residents of Emilia-Romagna at the end of 2011, 449,163 (12.1%) were hospitalized in 2012; 4.2% were hospitalized for the selected conditions or died in 2012 (3.6% hospitalized, 1.3% died). The C-statistic for the model predicting 2012 outcomes was 0.856. The model was well calibrated across categories of predicted risk. For those patients in the highest predicted risk decile group, the average predicted risk was 23.9% and the actual prevalence of hospitalization or death was 24.2%.

Conclusions: We have developed a population-based model using a longitudinal administrative database that identifies the risk of hospitalization for residents of the Emilia-Romagna region

1
2
3 with a level of performance as high as, or higher than, similar models. The results of this
4
5 model, along with profiles of patients identified as high risk are being provided to the physicians
6
7 and other health care professionals associated with the Patient Centered Medical Homes to aid in
8
9 planning for care management and interventions that may reduce their patients' likelihood of a
10
11 preventable, high-cost hospitalization.
12
13

14 15 16 17 18 **Strengths and Limitations of this study:** 19

- 20 • This study included the entire adult population of the Emilia-Romagna region of Italy,
21 over 3.7 million people.
- 22 • The study used an existing longitudinal administrative health care database with both the
23 advantage of much lower cost than new data collection and the disadvantage of potential
24 errors in administrative data.
- 25 • The results of the study are being used to assist in the development of newly formed
26 Patient Centered Medical Homes.

Introduction

The predominant healthcare delivery system, which has been a passive model, reacting to patients' problems, is shifting to a more proactive model designed to take the initiative in providing care for an increasingly older population that has a greater prevalence of chronic conditions, often with multiple medical and social needs. These changes are driving the reorganization of the primary care system, emphasizing coordination and cooperation among healthcare professionals.¹ Among the approaches to addressing this need has been the establishment of primary care organizations incorporating integrated teams of physicians and other healthcare professionals that “seek to increase the influence of primary care professionals, and in particular general practitioners (GPs), in health planning and resource allocation.”² Prominent among these new models of primary care is the Patient Centered Medical Home, an organization in which a team of healthcare providers is engaged in delivering comprehensive, coordinated, patient-centered care to patient defined populations.³

Primary care has a central role in the Italian National Health Service (NHS). Twenty one regional governments are responsible for ensuring the delivery of a health benefits package through a network of geographically defined, population-based Local Health Authorities. Primary care physicians work for these authorities as independent contractors and act as “gatekeepers” for specialty and other referral services for their patients.⁴

With the belief that a strong primary care system is conducive to improving population health, the NHS initiated reforms that encouraged primary care physicians to organize into collaborative arrangements. To this end, the Regione Emilia-Romagna (RER), a large northern region with a population of about 4.5 million, has recently launched a plan in its 11 Local Health Authorities to

1
2
3 establish Patient-Centered Medical Homes to better coordinate patient care and help patients
4
5 avoid unnecessary hospitalizations.
6
7

8
9 The identification of those patients who would benefit most from outreach efforts is fundamental
10
11 to achieving these goals of promoting and practicing population health in Patient-Centered
12
13 Medical Homes. To accomplish this, predictive models and risk stratification tools are needed to
14
15 identify patients at risk of a worsening of their health status. According to Knutson and Bella,⁵
16
17 “Predictive models are data-driven, decision-support tools that estimate an individual’s future
18
19 potential health care costs and/or opportunities for care management.” A good model will
20
21 identify as many of these patients as possible while excluding those for whom these interventions
22
23 would be unnecessary or ineffective.
24
25
26
27

28
29 The RER has established three objectives for this project: 1) develop predictive models to
30
31 identify patients at high risk of a progression of their medical problems or who are at risk of
32
33 developing new medical problems, 2) create “risk of hospitalization” patient profiles that provide
34
35 information about their high-risk patients to the general practitioners in the newly formed
36
37 Patient-Centered Medical Homes, and 3) assess the extent to which these models and reports
38
39 provide additional information useful in the identification of patients who may benefit from case
40
41 management or disease management.
42
43
44
45

46
47 This paper will address the first of the three goals. We describe the development of a predictive
48
49 model using the RER’s regional longitudinal administrative health care database to help identify
50
51 patients who are most at risk of hospitalization for conditions that may be impacted through
52
53 improved patient care. This model will then be used to inform the providers associated with the
54
55 Patient-Centered Medical Homes and aid in their planning for care management and
56
57

1
2
3 interventions that can reduce their patients' likelihood of a preventable, high-cost hospitalization.

8 Methods

9 Study Data and Study Population

10
11
12
13
14 The model was developed using the population-based longitudinal health care database of the
15 residents served by the RER Health Service in the years 2004 through 2012.⁶ This
16 administrative database includes demographic information for all residents (gender, birth and
17 death dates, location of current residence, and primary care physician), hospital discharge
18 abstract data (ICD-9-CM diagnosis and procedure codes, and admission and discharge dates),
19 emergency room utilization information, outpatient pharmacy data at the individual prescription
20 level, specialty care (laboratory, diagnostics, therapeutic procedures, rehabilitation, and specialist
21 visits), home health data, and information on each primary care physician in the region. Each
22 patient has an anonymous identifier assigned by the RER so that an individual's utilization can
23 be tracked over time without jeopardizing patient privacy.
24
25
26
27
28
29
30
31
32
33
34
35
36
37

38 The study population consisted of all residents of the RER who were at least 18 years of age and
39 still alive as of 31st December 2011.
40
41
42
43
44
45
46

47 Dependent Variable

48
49 The dependent variable was defined as the occurrence of a hospitalization for problems that are
50 potentially avoidable, or whose progression may have been avoided or delayed through
51 appropriate patient care, or the death of the individual for any reason in 2012. We decided to not
52
53
54
55
56
57
58
59
60

1
2
3 limit the hospitalization to emergency admissions, since a planned admission may also be an
4
5 indicator of a worsening medical problem. In order to operationally define the dependent
6
7 variable, we reviewed the Disease Staging^{7,8} primary diagnostic category and severity stage of
8
9 all day and inpatient hospital admissions (for adults age 18+) in RER for one year, to select those
10
11 admissions that should be included in the dependent variable.
12
13

14
15 Deliveries, admission for dental diseases or admissions for vague signs or symptoms with no
16
17 identified etiology were excluded. Admissions for problems that are not predictable/preventable
18
19 were excluded while those where screening may identify problems that can potentially be treated
20
21 to avoid progression were included. For example, admissions for stage 1, chronic cholecystitis
22
23 or cholelithiasis were excluded, but admissions for advanced stage 2 or 3 complications such as
24
25 ascending cholangitis or pancreatitis were included.
26
27
28

29
30 We felt that inclusion of hospitalization for cancer in the dependent variable should depend on
31
32 the ability to either prevent or avoid progression of the disease. We therefore included colon
33
34 cancer and cervical cancer in the definition because they are potentially preventable but excluded
35
36 all other cancers where prevention/prediction is not currently possible.
37
38
39

40
41 Inclusion of injuries, burns, or toxic reaction to prescription or non-prescription drugs would
42
43 ideally be based on the cause of these problems. Since the etiology of these problems is typically
44
45 not available in the administrative data being used in this project, we made the decision to
46
47 include or exclude based on our subjective judgment of the likelihood of preventability. For
48
49 example, adverse drug reactions were included but burns were excluded from the definition of
50
51 the dependent variable.
52
53
54
55
56
57
58
59
60

1
2
3 There is no obvious medical reason for a hospital admission for patients with stage 1 diabetes
4 mellitus or stage 1 essential hypertension without complications. These problems are typically
5 treatable in the outpatient setting. A hospitalization implies a potential problem in the care of
6 these patients, so we decided to include these admissions as a part of the dependent variable.⁹
7
8
9
10
11
12

13 14 15 16 17 18 Independent Variables 19

20 A broad range of candidate predictor variables was developed taking advantage of the RER
21 administrative data. The independent variables used for modeling were defined from the RER
22 administrative data for the years 2004 through 2011. Demographic data included patient age,
23 sex, and geographic location of residence. We developed a mapping to broad disease categories
24 defined primarily in terms of the affected body system from home health care data, pharmacy
25 data, and hospital discharge abstract data. (See Appendix.)
26
27
28
29
30
31
32
33
34
35
36

37 For those patients who had been hospitalized, more specific diagnostic data were available. We
38 reviewed the classification of patients hospitalized historically using the Disease Staging
39 diagnostic category and disease severity stages.^{7,8} Based on the frequencies specific diagnostic
40 category/stage predictor variables were defined for either specific stages of frequent diseases, or
41 by combinations across similar categories. Predictor variables were defined based on the number
42 of emergency room visits using the RER classifications system for the urgency of the visit.
43
44
45
46
47
48
49
50
51
52

53 Pharmacy data were used to identify polypharmacy¹⁰ (defined as the simultaneous use of five or
54 more active ingredients for at least 15 consecutive days), potential drug-drug interactions
55
56
57
58
59
60

1
2
3 (DDI)¹¹ and potentially inappropriate medication use in patients¹² 65 years and older. Since
4
5 cardiovascular disease is highly prevalent, we reviewed the use of cardiovascular drugs and
6
7 created a variable for each of the following 11 classes of drugs (oral anti-coagulants, beta-
8
9 blockers, angiotensin converting enzyme / angiotensin II receptor blockers, anti-platelets,
10
11 calcium channel blockers, anti-arrhythmics, digitalis glycosides, nitrates, diuretics, alfa-blockers,
12
13 statins) to account for the complexity of therapeutic regimen at the patient level.
14
15
16

17
18
19 To take advantage of the fact that the RER database includes multiple years of data, we created
20
21 history variables using the utilization for each year of data available. Since we were working
22
23 with the 2011 data to predict hospitalization or death in 2012, we created history variables based
24
25 on 2004-2010 data. This set included 83 of the diagnostic category/stage variables as well as 11
26
27 variables based on pharmacy utilization such as exposure to polypharmacy and use of
28
29 cardiovascular drugs. If the individual had a history of a disease in any of the years from 2004 to
30
31 2010 they were flagged as having a history of that disease and this was used as a potential
32
33 predictor variable.
34
35
36
37
38
39
40

41 Modeling

42
43
44 Logistic regression models were used to estimate predicted probabilities for the occurrence of an
45
46 inpatient hospital stay for the selected conditions or death for individual patients. Risk of
47
48 hospitalization or death, and the variables that relate to those risks are highly dependent on age
49
50 and gender. Regression models were fit in each of 14 gender and age strata using SAS Version
51
52 9.2 (SAS Institute, Cary NC). A stepwise process with relaxed entry and retention criteria
53
54
55
56
57
58
59
60

1
2
3 (inclusion p-value ≤ 0.8 , retention ≤ 0.5) was used for selecting a reduced, but robust set of
4
5 independent variables for the model in each age/gender stratum.
6
7
8
9

10 11 12 Evaluation of the Models 13

14
15 The predictive accuracy of the modelling was evaluated using C-statistics (the area under the
16
17 receiver operating characteristics curve), along with three measures traditionally used with
18
19 clinical screening tools: sensitivity, specificity and positive predictive value.
20
21

22
23 C-statistics were used to evaluate the models in two ways. The first evaluation consisted of
24
25 fitting the model developed using utilization and demographic data from 2011, along with
26
27 historical variables based on 2004-2010 data, and outcomes (hospitalization or death) from 2012
28
29 and then computing a C-statistic to evaluate how the models performed at predicting those
30
31 outcomes on which the models were conditioned. However, this evaluation is not consistent with
32
33 evaluating how the data are used in practice. In practice, we have current predictor information,
34
35 but the outcomes have not been realized. To better estimate how the models are likely to perform
36
37 in this setting, we fit models to outcomes data up to a year prior to the most current available
38
39 (e.g., 2011 outcomes modelled with predictors from 2010, along with historical variables based
40
41 on 2004-2009 data). We then computed a C-statistic for projections made on the risk of
42
43 hospitalization or death outcomes (in 2012) using the next year's predictor information (in 2011).
44
45 This way, the models are forced to make projections into the future, but we have the actual
46
47 observed outcomes data to evaluate the modelling process as it would be used in practice. The
48
49 resulting C-statistics obtained from these two model runs were compared.
50
51
52
53
54
55
56
57
58
59
60

1
2
3 In order to evaluate the performance of the model across different risk thresholds we classified
4 predicted risk scores. “Very high risk” was defined as patients with a predicted risk of
5 hospitalization or death in the following year of $\geq 25\%$ while “high risk” was defined as patients
6 with a predicted risk of hospitalization of 15-24%. These risk thresholds were selected after
7 consultation with physicians practicing in the medical homes to yield a total of about 10% of the
8 1,500 patients enrolled with a typical primary care physician.

17 **Results**

18
19
20 Among the 3,726,380 adult residents of Emilia Romagna at the end of 2011, 449,163 (12.1%)
21 were hospitalized in 2012; 4.2% were hospitalized for the selected conditions defined earlier or
22 died in 2012 (3.6% hospitalized, 1.3% died).
23
24
25
26
27
28

29 Table 1 shows the distribution of the demographics (age and gender), number of chronic
30 conditions, body systems impacted by the selected chronic conditions, polypharmacy and
31 inappropriate prescribing among the eligible RER residents, as of December 31, 2011. The
32 table also compares these characteristics of the total adult population of the region to the
33 subgroups of the population classified in the “very high risk” and “high risk” categories. Based
34 on the model results, 114,255 individuals were identified as having a predicted risk of
35 hospitalization or death in 2012 of $\geq 25\%$ and classified as “very high risk.” An additional
36 134,610 individuals had a predicted risk of hospitalization or death in 2012 of 15-24% and were
37 classified as “high risk.”

---	---------	-------	--------	-------	--------	-------

* Adults (age 18 or older) and alive at 31 December 2011.

** "Very high risk" was defined as patients with a predicted risk of hospitalization or death in the following year of > 25% while "high risk" was defined as patients with a predicted risk of hospitalization of 15-24%.

Men only.

Women only.

^ Polypharmacy is defined as the simultaneous use of five or more active ingredients for at least 15 consecutive days.

^^ The list of potentially inappropriate medications can be found in: Maio V, Del Canale S, Abouzaid S. Using Explicit Criteria to Evaluate the Quality of Prescribing in Elderly Italian Outpatients: A Cohort Study. *Journal of Clinical Pharmacy and Therapeutics* 2010;35:219-229.

There was little difference across the risk categories by gender. Age distributions for the "very high risk" and "high risk" groups were shifted more towards the older age groups than those in the overall study population. Residents age 85 or older represented about 4.5% of the RER population, but about 50% of the "very high" and "high" predicted risk groups. More than 75% of the residents over age 85 were classified as "very high" or "high" risk. However, age alone was not sufficient to their predict risk. For example, residents between 75 and 84 years of age made up 23% of the "very high" risk group and 41% of the "high" risk group, but over 85% of the residents in this age category had neither "very high" nor "high" predicted risk.

Across age and gender strata, demographics and health care utilization experience in 2011 were the most commonly used independent variables for predicting hospitalization or death in 2012. Selected history variables flagging chronic problems such as cardiovascular disease, diabetes mellitus and chronic renal failure and a history of prescriptions for cardiovascular medications and polypharmacy were also significant predictors.

1
2
3 The residents in the two higher risk groups were more likely than others to have multiple chronic
4 diseases and to experience polypharmacy and inappropriate medication use. The residents
5 identified as “very high risk” or “high risk” by the model also showed a number of striking
6 differences from others in terms of the occurrence of some of the most prevalent health
7 conditions by type and body system. Although cardiovascular conditions were not uncommon in
8 the total adult population (26.0%), they were far more common among those classified as “very
9 high risk” and “high risk” (84.2% and 77.1%, respectively). Similarly, gastrointestinal conditions
10 affected 15.6% of the total population, but were diagnosed in 65.4% of the “very high risk” and
11 49.3% of the “high risk” patients. Cancer occurred in 2.7% of the total population, but 20.9% of
12 the “very high risk” and 10.6% of the “high risk” patients had a cancer diagnosis. Mental health
13 problems were identified in 7.8% of the adult population, but in 34.2% of the “very high risk”
14 and 25.0% of the “high risk” patients.

30
31
32 The C-statistic for the model of 2012 outcomes developed using 2011 predictors and the
33 C-statistic based on the parameters from the model of 2011 outcomes regressed on 2010
34 predictors applied to the 2011 predictors and 2012 outcomes, were very similar (0.856 and 0.853,
35 respectively). These results suggest that the relationship between predictors and risk of
36 hospitalization changed little in one year and that model parameters developed in a prior year can
37 be used reliably with the most current year’s data to predict unknown outcomes in the next year
38 with only a minimal loss in performance in this population.

39
40
41
42
43
44
45
46
47
48
49
50 Table 2 shows the sensitivity, specificity, positive predictive value and number of true positives
51 for the model at the two selected cut-off points. The sensitivity (percentage of patients actually
52 hospitalized who had been identified by the model as having a predicted risk higher than the cut-
53
54
55
56

off point) was 29.8% for those with the “very high” risk scores. This percentage represents 46,950 of the 157,550 residents of the region who were hospitalized for a selected condition or died in 2012. If we modify the risk score threshold to include individuals with a predicted risk of hospitalization for selected conditions or death of $\geq 15\%$ (i.e., both the “very high risk” and the “high risk” patients) the sensitivity is .471. The true negative rate (specificity) is very high for both risk thresholds (.981 and .951, respectively).

Measure	Cut-off points for comparison	
	"Very high risk"*	"Very high risk"* + "High risk"**
Sensitivity ³	0.298	0.471
Specificity ⁴	0.981	0.951
Positive Predictive Value ⁵	0.411	0.298
True positives ⁶	46,950	74,196

* "Very high risk" is defined as patients with a predicted risk of hospitalization of $\geq 25\%$.
 ** "Very high risk" + "High risk", is defined as patients with a predicted risk of hospitalization of $\geq 15\%$.
 # Sensitivity is defined as the proportion of those hospitalized who were predicted to be hospitalized (true positive rate).
 ## Specificity is the proportion of those not hospitalized who were not predicted to be hospitalized (true negative rate).
 ^ Positive Predictive Value is the proportion of those predicted to be hospitalized who were actually hospitalized.
 ^^ True positives are the number of residents who were predicted to be at risk for hospitalization at the predicted risk threshold and were actually hospitalized.

The model appears to be well calibrated across levels of risk. The Figure depicts the RER population divided into groups by deciles of predicted risk of hospitalization or death from the models. The observed prevalence of hospitalization or death is compared to the average predicted risk among individuals in each of the ten predicted risk groups. For example, the

overall rate of hospitalization for the selected conditions or death in 2012 was 4.2%. For those patients in the highest predicted risk decile group, the average predicted risk was 23.9% and the actual prevalence of hospitalization or death was 24.2%.

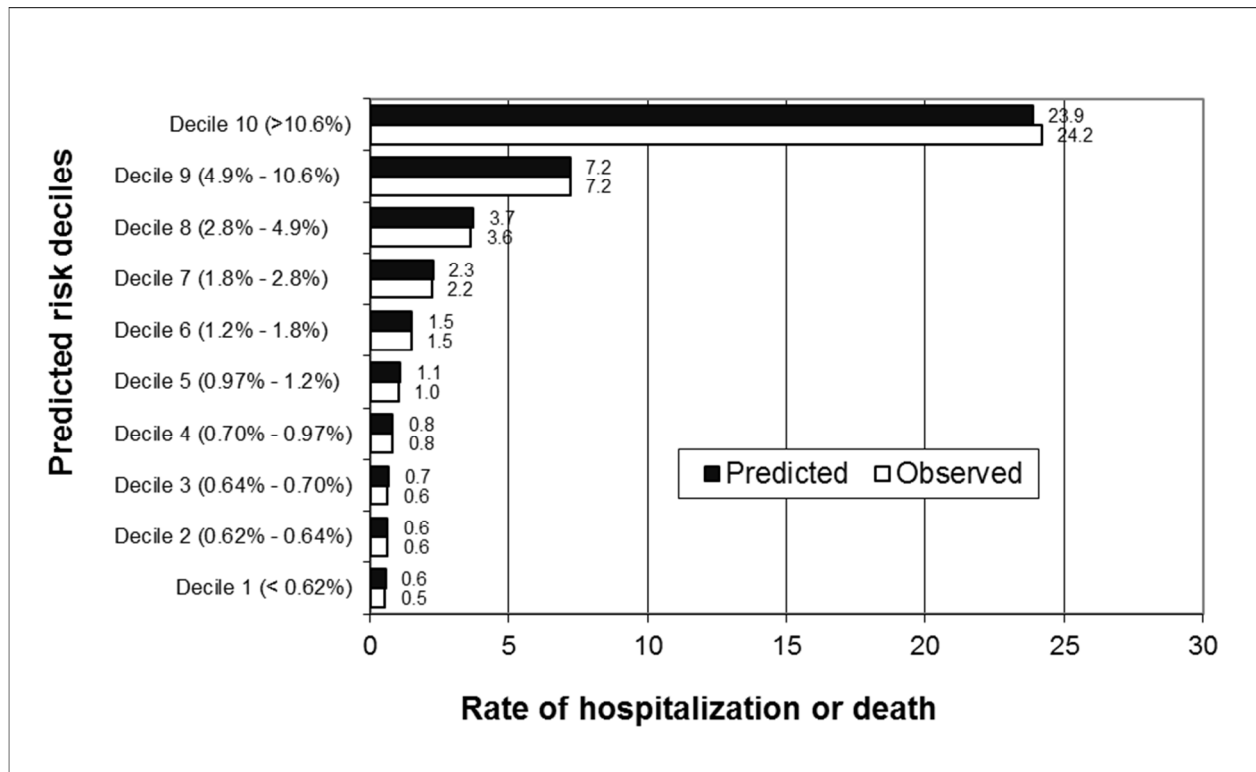

Figure. Model calibration: Predicted risk and observed prevalence of hospitalization or death in 2012 by predicted risk decile groups.

Discussion

We have developed a population-based model that identifies the risk of hospitalization for all adult RER residents and does so with a level of performance ($c=0.85$) as high as, or higher than, similar models. In addition, we believe that the definition of the dependent variable chosen for our models increases the probability that they are identifying patients who risk can potentially be improved by appropriate care. A systematic review by Kansagara¹³ of models designed to

1
2
3 predict readmissions, showed C-statistic results in the range of 0.55 to 0.83. Recent work by
4
5 Billings et al¹⁴ to develop models predictive of emergent admissions in the UK had results
6
7 ranging from 0.73 to 0.78. Li Wang, et al. (2013),¹⁵ using information available through the US
8
9 Veteran's Administration that also included lab data, demonstrated c-statistics of 0.81 and 0.79,
10
11 respectively, for their models of 90-day or 12-month hospitalization or death outcomes.
12
13

14
15
16 Although previous studies have developed models predictive of hospital care, these models fall
17
18 short of the needs of the Patient Centered Medical Homes being implemented in RER. Typically,
19
20 these models have focused on specific age groups,¹⁶ conditions, or types of admissions, such as
21
22 emergent¹⁴ or unplanned admissions or rehospitalizations, or health insurance plans in the United
23
24 States, including private insurance plans, Medicare and Medicaid plans.^{17,18} The models we have
25
26 developed are applied to the entire adult population of RER. They use existing administrative
27
28 data, which makes them cost effective to apply.
29
30
31

32
33 Patient Centered Medical Homes, including those instituted in RER, are responsible for
34
35 addressing the needs of their population and making the best use of their finite resources to
36
37 accomplish this. Preventing unnecessary admissions could improve both the quality of care and
38
39 health status of the enrolled population, and result in a substantial savings. To accomplish this,
40
41 predictive models and risk stratification tools such as those developed for this project are needed
42
43 to identify patients at risk of preventable admissions and provide information that can be used by
44
45 the medical homes to help manage care.
46
47
48

49
50 There are some limitations to the model. The model is developed from administrative data.

51
52 Administrative data are collected for reimbursement and tracking utilization and not for medical
53
54 research. They lack the clinical specificity that would be desirable in assessing an individual's
55
56

1
2
3 medical problems. While the hospital discharge abstract data do include diagnostic information
4 coded using ICD-9-CM, no similar data are available for outpatient encounters in the RER
5
6
7
8 database. In addition, our models use prior utilization among the predictor variables. With the
9
10 administrative data we cannot distinguish between appropriate and inappropriate treatment which
11
12 may bias our results.
13

14
15
16 Despite the limitations of administrative data, they have many advantages for this project: they
17
18 are readily available, relatively inexpensive to analyze and cover large populations over many
19
20 years. They are ideal for uncovering patterns of care. If information from the medical records is
21
22 needed, the results of these analyses can then be supplemented by focused clinical reviews at the
23
24 local level. Also, The RER has a system in place to monitor the quality of diagnosis and
25
26 procedure coding in their hospital discharge abstract data. Controls at both the hospital and
27
28 regional level assess the validity of coding and the consistency of codes assigned such as
29
30 congruity between sex, age and diagnosis and between diagnosis and procedure. The existence
31
32 of the RER administrative database made it feasible to develop the models described in this
33
34 article at relatively low cost and to update the models over time without additional data
35
36 collection that others have found necessary.¹⁴
37
38
39
40
41
42

43 Currently, these risk scores are being integrated with other information in profiles of high-risk
44
45 patients furnished to providers in 12 newly formed medical homes, including 83 primary care
46
47 physicians serving a total of about 100,000 patients, in the Parma Local Health Authority located
48
49 in RER. Along with the risk scores, this information includes data about previous
50
51 hospitalizations, use of referrals, medications, long-term care and home care services, and a
52
53 number of process-like quality indicators for diabetic and cardiovascular patients, and for
54
55
56
57
58
59
60

1
2
3 appropriate medication use in older patients. An evaluation of the use and usefulness of these
4
5 profiles is under way.
6
7

8
9 In summary, these models provide a means of identifying patients at high risk for hospitalization.
10
11 The risk predictions, in conjunction with the risk profile, show promise as a useful organizational
12
13 tool for the regional Patient Centered Medical Homes to develop and implement proactive case
14
15 management and disease management programs. The RER is reviewing the results of the Parma
16
17 Local Health Authority pilot project of the profiles. Once their usefulness has been further
18
19 evaluated, their use will be expanded to other Medical Homes in development in the other Local
20
21 Health Authorities in the Emilia-Romagna region. If similar data are available, these models can
22
23 be applied in other Italian regions and other countries investing in organization similar to the
24
25 Patient Centered Medical Home.

Ethical approval: This study was approved by the Institutional Review Board of Thomas Jefferson University as an expedited retrospective database/record review. The IRB granted a waiver of informed consent.

Contributorship Statement: DZL, RG, VM, and JSG were responsible for the conceptualization of this project. MR, JM, and ML were responsible for creation of the data sets used in this project. DZL, VM, MR, and JSG were responsible for the definition of analytical variables. SWK, MR, ML and JM were responsible for modeling and statistical analysis. DZL managed the research team. RG and JSG advised on the analyses and results. All authors contributed to the preparation of the manuscript.

Competing interests: All authors have completed the Unified Competing Interest form and declare grants from the Regione Emilia-Romagna (Louis, Robeson, McAna, Maio, Keith, Liu, Gonnella) during the conduct of the study. Louis and Gonnella declare personal fees from Truven Health Analytics, The National School of Public Health, Portugal, INSIEL Mercato.

Data Sharing Statement: No additional data

Predicting Risk Using a Population Based Longitudinal Database

Louis et al

STROBE Statement—checklist of items that should be included in reports of observational studies

	Item No	Recommendation	
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	See abstract section: Design.
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	The outcome measures used and what was found are summarized in the sections of the abstract: Main outcome measures and Results
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	See the Introduction section pages 4 and 5
Objectives	3	State specific objectives, including any prespecified hypotheses	Our objectives are described in the last two paragraphs of the Introduction
Methods			
Study design	4	Present key elements of study design early in the paper	See last paragraph of the Introduction and the Methods section
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	See <u>Study Data and Study Population</u> at beginning of Methods section
Participants	6	(a) <i>Cohort study</i> —Give the eligibility criteria, and the sources and methods of selection of participants. Describe methods of follow-up <i>Case-control study</i> —Give the eligibility criteria, and the sources and methods of case ascertainment and control selection. Give the rationale for the choice of cases and controls <i>Cross-sectional study</i> —Give the eligibility criteria, and the sources and methods of selection of participants	Our study includes 100% of the adult population See <u>Study Data and Study Population</u> at beginning of Methods section
		(b) <i>Cohort study</i> —For matched studies, give matching criteria and number of exposed and unexposed <i>Case-control study</i> —For matched studies, give matching criteria and the number of controls per case	
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	See the Dependent variable and Independent variable sections in the Methods section
Data sources/ measurement	8*	For each variable of interest, give sources of data	See the Dependent variable

		and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	and Independent variable sections in the Methods section. In addition we have included an Appendix with detailed mapping to independent variable.
Bias	9	Describe any efforts to address potential sources of bias	See Evaluation of the Models (page 10) in the Methods section
Study size	10	Explain how the study size was arrived at	Our study includes 100% of the adult population
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	See the Dependent variable and Independent variable sections in the Methods section. In addition we have included an Appendix with detailed mapping to independent variable.
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	See the Modelling section and Evaluation of the Models section (pages 9 and 10) of the Methods
		(b) Describe any methods used to examine subgroups and interactions	See the Modelling section (pages 9 and 10) of the Methods
		(c) Explain how missing data were addressed	
		(d) <i>Cohort study</i> —If applicable, explain how loss to follow-up was addressed <i>Case-control study</i> —If applicable, explain how matching of cases and controls was addressed <i>Cross-sectional study</i> —If applicable, describe analytical methods taking account of sampling strategy	Our study includes 100% of the adult population
		(e) Describe any sensitivity analyses	See Evaluation of the Models last paragraph of Methods.
Results			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	See Page 11 Results section
		(b) Give reasons for non-participation at each stage	N/A
		(c) Consider use of a flow diagram	
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	See Table 1 and Results section (page 11-14)
		(b) Indicate number of participants with missing data for each variable of interest	

		(c) <i>Cohort study</i> —Summarise follow-up time (eg, average and total amount)	N/A
Outcome data	15*	<i>Cohort study</i> —Report numbers of outcome events or summary measures over time	
		<i>Case-control study</i> —Report numbers in each exposure category, or summary measures of exposure	
		<i>Cross-sectional study</i> —Report numbers of outcome events or summary measures	See Table 2 and figure and pages 14 and 15 of Results section
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	See pages 13
		(b) Report category boundaries when continuous variables were categorized	
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	See Table 2 and page 13 and 14.
Discussion			
Key results	18	Summarise key results with reference to study objectives	See Discussion section page 16
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	See Discussion section pages 17 and 18
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	See Discussion section page 18
Generalisability	21	Discuss the generalisability (external validity) of the study results	See Discussion section pages 18 and 19
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	The study was funded by the Emilia-Romagna, region of Italy. See page 3.

*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at <http://www.plosmedicine.org/>, Annals of Internal Medicine at <http://www.annals.org/>, and Epidemiology at <http://www.epidem.com/>). Abstract

Objectives: Develop predictive models using an administrative health care database that provide information for Patient Centered Medical Homes to proactively identify patients at risk of hospitalization for conditions that may be impacted through improved patient care.

Design: Retrospective health care utilization analysis with multivariate logistic regression models.

Data: A population-based longitudinal database of residents served by the Emilia-Romagna, Italy health service in the years 2004-2012 including demographic information and utilization of health services by 3,726,380 people age ≥ 18 years.

Outcome measures: Models designed to predict risk of hospitalization or death for problems that are potentially avoidable were developed and evaluated using the area under the receiver operating curve C-statistic, in terms of their sensitivity, specificity, and positive predictive value, and for calibration to assess performance across levels of predicted risk.

Results: Among the 3,726,380 adult residents of Emilia-Romagna at the end of 2011, 449,163 (12.1%) were hospitalized in 2012; 4.2% were hospitalized for the selected conditions or died in 2012 (3.6% hospitalized, 1.3% died). The C-statistic for the model predicting 2012 outcomes was 0.856. The model was well calibrated across categories of predicted risk. For those patients in the highest predicted risk decile group, the average predicted risk was 23.9% and the actual prevalence of hospitalization or death was 24.2%.

Conclusions: We have developed a population-based model using a longitudinal administrative database that identifies the risk of hospitalization for residents of the Emilia-Romagna region

1
2
3 with a level of performance as high as, or higher than, similar models. The results of this
4
5 model, along with profiles of patients identified as high risk are being provided to the physicians
6
7 and other health care professionals associated with the Patient Centered Medical Homes to aid in
8
9 planning for care management and interventions that may reduce their patients' likelihood of a
10
11 preventable, high-cost hospitalization.
12
13

14 15 16 17 18 **Strengths and Limitations of this study:** 19

- 20 • This study included the entire adult population of the Emilia-Romagna Region of Italy,
21 over 3.7 million people.
- 22 • The study used an existing longitudinal administrative health care database with both the
23 advantage of much lower cost than new data collection and the disadvantage of potential
24 errors in administrative data.
- 25 • The results of the study are being used to assist in the development of newly formed
26 Patient Centered Medical Homes.

Introduction

The predominant healthcare delivery system, which has been a passive model, reacting to patients' problems, is shifting to a more proactive model designed to take the initiative in providing care for an increasingly older population that has a greater prevalence of chronic conditions, often with multiple medical and social needs. These changes are driving the reorganization of the primary care system, emphasizing coordination and cooperation among healthcare professionals.¹ Among the approaches to addressing this need has been the establishment of primary care organizations incorporating integrated teams of physicians and other healthcare professionals that “seek to increase the influence of primary care professionals, and in particular general practitioners (GPs), in health planning and resource allocation.”² Prominent among these new models of primary care is the Patient Centered Medical Home, an organization in which a team of healthcare providers is engaged in delivering comprehensive, coordinated, patient-centered care to patient defined populations.³

Primary care has a central role in the Italian National Health Service (NHS). Twenty one regional governments are responsible for ensuring the delivery of a health benefits package through a network of geographically defined, population-based Local Health Authorities. Primary care physicians work for these authorities as independent contractors and act as “gatekeepers” for specialty and other referral services for their patients.⁴

With the belief that a strong primary care system is conducive to improving population health, the NHS initiated reforms that encouraged primary care physicians to organize into collaborative arrangements. To this end, the Regione Emilia-Romagna (RER), a large northern region with a population of about 4.5 million, has recently launched a plan in its 11 Local Health Authorities to

1
2
3 establish Patient-Centered Medical Homes to better coordinate patient care and help patients
4
5 avoid unnecessary hospitalizations.
6
7

8
9 The identification of those patients who would benefit most from outreach efforts is fundamental
10
11 to achieving these goals of promoting and practicing population health in Patient-Centered
12
13 Medical Homes. To accomplish this, predictive models and risk stratification tools are needed to
14
15 identify patients at risk of a worsening of their health status. According to Knutson and Bella,⁵
16
17 “Predictive models are data-driven, decision-support tools that estimate an individual’s future
18
19 potential health care costs and/or opportunities for care management.” A good model will
20
21 identify as many of these patients as possible while excluding those for whom these interventions
22
23 would be unnecessary or ineffective.
24
25
26
27

28
29 The RER has established three objectives for this project: 1) develop predictive models to
30
31 identify patients at high risk of hospitalization or death, 2) create “risk of hospitalization” patient
32
33 profiles that provide information about their high-risk patients to the general practitioners in the
34
35 newly formed Patient-Centered Medical Homes, and 3) assess the extent to which these models
36
37 and reports provide additional information useful in the identification of patients who may
38
39 benefit from case management or disease management.
40
41
42

43
44 This paper will address the first of the three goals. We describe the development of a predictive
45
46 model using the RER’s regional longitudinal administrative health care database to help identify
47
48 patients who are most at risk of hospitalization for conditions that may be impacted through
49
50 improved patient care. This model will then be used to inform the providers associated with the
51
52 Patient-Centered Medical Homes and aid in their planning for care management and
53
54 interventions that can reduce their patients’ likelihood of a preventable, high-cost hospitalization.
55
56
57

Methods

Study Data and Study Population

The model was developed using the population-based longitudinal health care database of the residents served by the RER Health Service in the years 2004 through 2012.⁶ This administrative database includes demographic information for all residents (gender, birth and death dates, location of current residence, and primary care physician), hospital discharge abstract data (ICD-9-CM diagnosis and procedure codes, and admission and discharge dates), emergency room utilization information, outpatient pharmacy data at the individual prescription level, specialty care (laboratory, diagnostics, therapeutic procedures, rehabilitation, and specialist visits), home health data, and information on each primary care physician in the region. Each patient has an anonymous identifier assigned by the RER so that an individual's utilization can be tracked over time without jeopardizing patient privacy.

The study population consisted of all residents of the RER who were at least 18 years of age and still alive as of 31st December 2011.

Dependent Variable

The dependent variable was defined as the occurrence of a hospitalization for problems that are potentially avoidable, or whose progression may have been avoided or delayed through appropriate patient care, or the death of the individual, either in or out of the hospital, for any reason in 2012. We decided to not limit the hospitalization to emergency admissions, since a planned admission may also be an indicator of a worsening medical problem. In order to

1
2
3 operationally define the dependent variable, we (authors JSG and DZL) reviewed the Disease
4 Staging^{7,8} primary diagnostic category and severity stage of all day and inpatient hospital
5 admissions (for adults age 18+) in RER for one year, to select those admissions that should be
6 included in the dependent variable.
7
8
9
10
11

12
13 Deliveries, admission for dental diseases or admissions for vague signs or symptoms with no
14 identified etiology were excluded. Admissions for problems that are not predictable/preventable
15 were excluded while those where screening may identify problems that can potentially be treated
16 to avoid progression were included. For example, admissions for stage 1, chronic cholecystitis
17 or cholelithiasis were excluded, but admissions for advanced stage 2 or 3 complications such as
18 ascending cholangitis or pancreatitis were included.
19
20
21
22
23
24
25
26

27
28 We felt that inclusion of hospitalization for cancer in the dependent variable should depend on
29 the ability to either prevent or avoid progression of the disease. We therefore included colon
30 cancer and cervical cancer in the definition because they are potentially preventable but excluded
31 all other cancers where prevention/prediction is not currently possible.
32
33
34
35
36
37

38
39 Inclusion of injuries, burns, or toxic reaction to prescription or non-prescription drugs would
40 ideally be based on the cause of these problems. Since the etiology of these problems is typically
41 not available in the administrative data being used in this project, we made the decision to
42 include or exclude based on our subjective judgment of the likelihood of preventability. For
43 example, adverse drug reactions were included but burns were excluded from the definition of
44 the dependent variable.
45
46
47
48
49
50
51
52

1
2
3 There is no obvious medical reason for a hospital admission for patients with stage 1 diabetes
4 mellitus or stage 1 essential hypertension without complications. These problems are typically
5 treatable in the outpatient setting. A hospitalization implies a potential problem in the care of
6 these patients, so we decided to include these admissions as a part of the dependent variable.⁹
7
8
9
10
11
12

13 14 15 16 17 18 Independent Variables 19

20 A broad range of candidate predictor variables was developed taking advantage of the RER
21 administrative data. The independent variables used for modeling were defined from the RER
22 administrative data for the years 2004 through 2011. Demographic data included patient age,
23 sex, and geographic location of residence. We developed a mapping to broad disease categories
24 defined primarily in terms of the affected body system from home health care data, pharmacy
25 data, and hospital discharge abstract data. (See Appendix 1.)
26
27
28
29
30
31
32
33
34
35
36

37 For those patients who had been hospitalized, more specific diagnostic data were available. We
38 reviewed the classification of patients hospitalized historically using the Disease Staging
39 diagnostic category and disease severity stages.^{7,8} Based on the frequencies specific diagnostic
40 category/stage predictor variables were defined for either specific stages of frequent diseases, or
41 by combinations across similar categories. Predictor variables were defined based on the number
42 of emergency room visits using the RER classifications system for the urgency of the visit.
43
44
45
46
47
48

52

53 Pharmacy data were used to identify polypharmacy¹⁰ (defined as the simultaneous use of five or
54 more active ingredients for at least 15 consecutive days), potential drug-drug interactions
55
56
57
58
59
60

1
2
3 (DDI)¹¹ and potentially inappropriate medication use in patients¹² 65 years and older. Since
4 cardiovascular disease is highly prevalent, we reviewed the use of cardiovascular drugs and
5 created a variable for each of the following 11 classes of drugs (oral anti-coagulants, beta-
6 blockers, angiotensin converting enzyme / angiotensin II receptor blockers, anti-platelets,
7 calcium channel blockers, anti-arrhythmics, digitalis glycosides, nitrates, diuretics, alfa-blockers,
8 statins) to account for the complexity of therapeutic regimen at the patient level.

10
11
12
13
14
15
16

17
18
19 To take advantage of the fact that the RER database includes multiple years of data, we created
20 history variables using the utilization for each year of data available. Since we were working
21 with the 2011 data to predict hospitalization or death in 2012, we created history variables based
22 on 2004-2010 data. This set included 83 of the diagnostic category/stage variables as well as 11
23 variables based on pharmacy utilization such as exposure to polypharmacy and use of
24 cardiovascular drugs. If the individual had a history of a disease in any of the years from 2004 to
25 2010 they were flagged as having a history of that disease and this was used as a potential
26 predictor variable.

40

41 Modeling

42
43
44 Logistic regression models were used to estimate predicted probabilities for the occurrence of an
45 inpatient hospital stay for the selected conditions or death for individual patients. Risk of
46 hospitalization or death, and the variables that relate to those risks are highly dependent on age
47 and gender. Regression models were fit in each of 14 gender and age strata using SAS Version
48 9.2 (SAS Institute, Cary NC). A stepwise process with relaxed covariate entry and retention
49 criteria (inclusion p-value ≤ 0.8 , retention ≤ 0.5) was used. At each step in this process, an
50
51
52
53
54
55
56
57
58
59
60

1
2
3 attempt is made to remove any unimportant variables from the model before adding a potentially
4 important variable. Each addition or deletion of a variable to or from a potential model is a
5 separate step and, at each step, a new model is fitted. This process results in a reduced, but robust
6 set of independent variables that predict outcome or that might have importance as adjustment
7 terms for the model in each age/gender stratum.

14
15
16
17
18
19

20 Evaluation of the Models

21
22 The predictive accuracy of the modelling was evaluated using C-statistics (the area under the
23 receiver operating characteristics curve), along with three measures traditionally used with
24 clinical screening tools: sensitivity, specificity and positive predictive value.
25
26
27
28
29

30 C-statistics were used to evaluate the models in two ways. The first evaluation consisted of
31 fitting the model developed using utilization and demographic data from 2011, along with
32 historical variables based on 2004-2010 data, and outcomes (hospitalization or death) from 2012
33 and then computing a C-statistic to evaluate how the models performed at predicting those
34 outcomes on which the models were conditioned. However, this evaluation is not consistent with
35 evaluating how the data are used in practice. In practice, we have current predictor information,
36 but the outcomes have not been realized. To better estimate how the models are likely to perform
37 in this setting, we fit models to outcomes data up to a year prior to the most current available
38 (e.g., 2011 outcomes modelled with predictors from 2010, along with historical variables based
39 on 2004-2009 data). We then computed a C-statistic for projections made on the risk of
40 hospitalization or death outcomes (in 2012) using the next year's predictor information (in 2011).
41
42
43
44
45
46
47
48
49
50
51
52
53
54
55
56 This way, the models are forced to make projections into the future, but we have the actual
57
58
59
60

1
2
3 observed outcomes data to evaluate the modelling process as it would be used in practice. The
4
5 resulting C-statistics obtained from these two model runs were compared.
6
7

8
9 In order to evaluate the performance of the model across different risk thresholds we classified
10
11 predicted risk scores. “Very high risk” was defined as patients with a predicted risk of
12
13 hospitalization or death in the following year of $\geq 25\%$ while “high risk” was defined as patients
14
15 with a predicted risk of hospitalization of 15-24%. These risk thresholds were selected after
16
17 consultation with physicians practicing in the medical homes to yield a total of about 10% of the
18
19 1,500 patients enrolled with a typical primary care physician.
20
21

22 23 **Results**

24
25
26
27 Among the 3,726,380 adult residents of Emilia Romagna at the end of 2011, 449,163 (12.1%)
28
29 were hospitalized in 2012; 4.2% were hospitalized for the selected conditions defined earlier or
30
31 died in 2012 (3.6% hospitalized, 1.3% died).
32
33

34
35 Table 1 shows the distribution of the demographics (age and gender), number of chronic
36
37 conditions, body systems impacted by the selected chronic conditions, polypharmacy and
38
39 inappropriate prescribing among the eligible RER residents, as of December 31, 2011. The
40
41 table also compares these characteristics of the total adult population of the region to the
42
43 subgroups of the population classified in the “very high risk” and “high risk” categories. Based
44
45 on the model results, 114,255 individuals were identified as having a predicted risk of
46
47 hospitalization or death in 2012 of $\geq 25\%$ and classified as “very high risk.” An additional
48
49 134,610 individuals had a predicted risk of hospitalization or death in 2012 of 15-24% and were
50
51 classified as “high risk.”
52
53

Polypharmacy[^]	609,278	16.4%	92,153	80.7%	92,156	68.5%
Any potentially inappropriate medications (age 65 years or older)^{^^}	257,033	25.5%	51,055	48.7%	49,003	39.2%

* Adults (age 18 or older) and alive at 31 December 2011.

** "Very high risk" was defined as patients with a predicted risk of hospitalization or death in the following year of $\geq 25\%$ while "high risk" was defined as patients with a predicted risk of hospitalization of 15-24%.

Men only.

Women only.

[^] Polypharmacy is defined as the simultaneous use of five or more active ingredients for at least 15 consecutive days.

^{^^} The list of potentially inappropriate medications can be found in: Maio V, Del Canale S, Abouzaid S. Using Explicit Criteria to Evaluate the Quality of Prescribing in Elderly Italian Outpatients: A Cohort Study. *Journal of Clinical Pharmacy and Therapeutics* 2010;35:219-229.

There was little difference across the risk categories by gender. Age distributions for the "very high risk" and "high risk" groups were shifted more towards the older age groups than those in the overall study population. Residents age 85 or older represented about 4.5% of the RER population, but about 50% of the "very high" and "high" predicted risk groups. More than 75% of the residents over age 85 were classified as "very high" or "high" risk. However, age alone was not sufficient to their predict risk. For example, residents between 75 and 84 years of age made up 23% of the "very high" risk group and 41% of the "high" risk group, but over 85% of the residents in this age category had neither "very high" nor "high" predicted risk.

Across age and gender strata, demographics and health care utilization experience in 2011 were the most commonly used independent variables for predicting hospitalization or death in 2012. Selected history variables flagging chronic problems such as cardiovascular disease, diabetes mellitus and chronic renal failure and a history of prescriptions for cardiovascular medications and polypharmacy were also significant predictors.

1
2
3 The residents in the two higher risk groups were more likely than others to have multiple chronic
4 diseases and to experience polypharmacy and inappropriate medication use. The residents
5 identified as “very high risk” or “high risk” by the model also showed a number of striking
6 differences from others in terms of the occurrence of some of the most prevalent health
7 conditions by type and body system. Although cardiovascular conditions were not uncommon in
8 the total adult population (26.0%), they were far more common among those classified as “very
9 high risk” and “high risk” (84.2% and 77.1%, respectively). Similarly, gastrointestinal conditions
10 affected 15.6% of the total population, but were diagnosed in 65.4% of the “very high risk” and
11 49.3% of the “high risk” patients. Cancer occurred in 2.7% of the total population, but 20.9% of
12 the “very high risk” and 10.6% of the “high risk” patients had a cancer diagnosis. Mental health
13 problems were identified in 7.8% of the adult population, but in 34.2% of the “very high risk”
14 and 25.0% of the “high risk” patients.

15
16
17 The C-statistic for the model of 2012 outcomes developed using 2011 predictors and the
18 C-statistic based on the parameters from the model of 2011 outcomes regressed on 2010
19 predictors applied to the 2011 predictors and 2012 outcomes were very similar (0.856 and 0.853,
20 respectively). These results suggest that the relationship between predictors and risk of
21 hospitalization changed little in one year and that model parameters developed in a prior year can
22 be used reliably with the most current year’s data to predict unknown outcomes in the next year
23 with only a minimal loss in performance in this population.

24
25
26 Table 2 shows the sensitivity, specificity, positive predictive value and number of true positives
27 for the model at the two selected cut-off points. The sensitivity (percentage of patients actually
28 hospitalized who had been identified by the model as having a predicted risk higher than the cut-
29

off point) was 29.8% for those with the “very high” risk scores. This percentage represents 46,950 of the 157,550 residents of the region who were hospitalized for a selected condition or died in 2012. If we modify the risk score threshold to include individuals with a predicted risk of hospitalization for selected conditions or death of $\geq 15\%$ (i.e., both the “very high risk” and the “high risk” patients) the sensitivity is .471. The true negative rate (specificity) is very high for both risk thresholds (.981 and .951, respectively).

Measure	Cut-off points for comparison	
	"Very high risk"*	"Very high risk"* + "High risk"**
Sensitivity[#]	0.298	0.471
Specificity^{##}	0.981	0.951
Positive Predictive Value[^]	0.411	0.298
True positives^{^^}	46,950	74,196

* "Very high risk" is defined as patients with a predicted risk of hospitalization of $\geq 25\%$.
 ** "Very high risk" + "High risk", is defined as patients with a predicted risk of hospitalization of $\geq 15\%$.
 # Sensitivity is defined as the proportion of those hospitalized who were predicted to be hospitalized (true positive rate).
 ## Specificity is the proportion of those not hospitalized who were not predicted to be hospitalized (true negative rate).
 ^ Positive Predictive Value is the proportion of those predicted to be hospitalized who were actually hospitalized.
 ^^ True positives are the number of residents who were predicted to be at risk for hospitalization at the predicted risk threshold and were actually hospitalized.

The model appears to be well calibrated across levels of risk. The Figure depicts the RER population divided into groups by deciles of predicted risk of hospitalization or death from the models. The observed prevalence of hospitalization or death is compared to the average predicted risk among individuals in each of the ten predicted risk groups. For example, the

1
2
3 overall rate of hospitalization for the selected conditions or death in 2012 was 4.2%. For those
4
5 patients in the highest predicted risk decile group, the average predicted risk was 23.9% and the
6
7 actual prevalence of hospitalization or death was 24.2%. (Regression coefficients and
8
9 significance levels of independent variables for models for each of 14 age and gender strata are
10
11 displayed in Appendix 2.)

18
19
20
21

22 **Discussion**

23
24 We have developed a population-based model that identifies the risk of hospitalization for all
25
26 adult RER residents and does so with a level of performance ($c=0.85$) as high as, or higher than,
27
28 similar models. In addition, we believe that the definition of the dependent variable chosen for
29
30 our models increases the probability that they are identifying patients who risk can potentially be
31
32 improved by appropriate care. A systematic review by Kansagara¹³ of models designed to
33
34 predict readmissions, showed C-statistic results in the range of 0.55 to 0.83. Recent work by
35
36 Billings et al¹⁴ to develop models predictive of emergent admissions in the UK had results
37
38 ranging from 0.73 to 0.78. Li Wang, et al. (2013),¹⁵ using information available through the US
39
40 Veteran's Administration that also included lab data, demonstrated c-statistics of 0.81 and 0.79,
41
42 respectively, for their models of 90-day or 12-month hospitalization or death outcomes. At a
43
44 predicted risk of $\geq 25\%$ our model had a Positive Predictive Value (PPV) of .411. Billings et al¹⁴
45
46 reported a PPV of .417 at a risk threshold of 30. There is a trade-off in using our model, or any
47
48 predictive model, between the threshold for follow-up and predictive accuracy. A lower risk
49
50 threshold would identify more patients but with a lower prevalence of hospitalization or death.
51
52
53
54
55
56
57

1
2
3 Although previous studies have developed models predictive of hospital care, these models fall
4 short of the needs of the Patient Centered Medical Homes being implemented in RER. Typically,
5 these models have focused on specific age groups,¹⁶ conditions, or types of admissions, such as
6 emergent¹⁴ or unplanned admissions or rehospitalizations, or health insurance plans in the United
7 States, including private insurance plans, Medicare and Medicaid plans.^{17,18} The models we have
8 developed are applied to the entire adult population of RER. They use existing administrative
9 data, which makes them cost effective to apply.
10
11
12
13
14
15
16
17
18
19

20 Patient Centered Medical Homes, including those instituted in RER, are responsible for
21 addressing the needs of their population and making the best use of their finite resources to
22 accomplish this. Preventing unnecessary admissions could improve both the quality of care and
23 health status of the enrolled population, and result in a substantial savings. To accomplish this,
24 predictive models and risk stratification tools such as those developed for this project are needed
25 to identify patients at risk of preventable admissions and provide information that can be used by
26 the medical homes to help manage care.
27
28
29
30
31
32
33
34
35
36
37

38 There are some limitations to the model. The model is developed from administrative data.
39 Administrative data are collected for reimbursement and tracking utilization and not for medical
40 research. They lack the clinical specificity that would be desirable in assessing an individual's
41 medical problems. While the hospital discharge abstract data do include diagnostic information
42 coded using ICD-9-CM, no similar data are available for outpatient encounters in the RER
43 database. The mortality data available for this project did not include information about cause
44 of death. Therefore, some proportion of patients whose death was not predictable were included,
45 limiting model performance. In addition, our models use prior utilization among the predictor
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 variables. With the administrative data we cannot distinguish between appropriate and
4
5 inappropriate treatment which may bias our results.
6
7

8
9 Despite the limitations of administrative data, they have many advantages for this project: they
10
11 are readily available, relatively inexpensive to analyze and cover large populations over many
12
13 years. They are ideal for uncovering patterns of care. If information from the medical records is
14
15 needed, the results of these analyses can then be supplemented by focused clinical reviews at the
16
17 local level. Also, The RER has a system in place to monitor the quality of diagnosis and
18
19 procedure coding in their hospital discharge abstract data. Controls at both the hospital and
20
21 regional level assess the validity of coding and the consistency of codes assigned such as
22
23 congruity between sex, age and diagnosis and between diagnosis and procedure. The existence
24
25 of the RER administrative database made it feasible to develop the models described in this
26
27 article at relatively low cost and to update the models over time without additional data
28
29 collection that others have found necessary.¹⁴
30
31
32
33
34

35
36 Currently, these risk scores are being integrated with other information in profiles of high-risk
37
38 patients furnished to providers in 12 newly formed medical homes, including 83 primary care
39
40 physicians serving a total of about 100,000 patients, in the Parma Local Health Authority located
41
42 in RER. Along with the risk scores, this information includes data about previous
43
44 hospitalizations, use of referrals, medications, long-term care and home care services, and a
45
46 number of process-like quality indicators for diabetic and cardiovascular patients, and for
47
48 appropriate medication use in older patients.
49
50
51

52
53 Of course, model results need to lead to an effective intervention to have a positive impact on
54
55 patient care. To this end, we are working with the physicians, nurses, and other health care
56
57

1
2
3 professionals as well as the administration of the newly formed Medical Homes in Parma to
4
5 assist them in understanding how to use the results of these models and in developing potentially
6
7 effective interventions. The individual profiles of high risk patients provided to the health care
8
9 team in the Medical Homes allow them to trigger specific actions such as inviting patients to
10
11 enroll in disease management programs for chronic problems such as heart failure, chronic
12
13 obstructive pulmonary disease, or diabetes mellitus, activating home health assistance, initiating
14
15 a medication review, or recommending that the patient come in for an office visit. An evaluation
16
17 of the use and usefulness of the profiles and intervention is under way.
18
19
20
21
22

23 In summary, these models provide a means of identifying patients at high risk for hospitalization.
24
25 The risk predictions, in conjunction with the risk profile, show promise as a useful organizational
26
27 tool for the regional Patient Centered Medical Homes to develop and implement proactive case
28
29 management and disease management programs. The RER is reviewing the results of the Parma
30
31 Local Health Authority pilot project of the profiles. Once their usefulness has been further
32
33 evaluated, their use will be expanded to other Medical Homes in development in the other Local
34
35 Health Authorities in the Emilia-Romagna region. If similar data are available, these models can
36
37 be applied in other Italian regions and other countries investing in organization similar to the
38
39 Patient Centered Medical Home.

Abstract

Objectives: Develop predictive models using an administrative health care database that provide information for Patient Centered Medical Homes to proactively identify patients at risk of hospitalization for conditions that may be impacted through improved patient care.

Design: Retrospective health care utilization analysis with multivariate logistic regression models.

Data: A population-based longitudinal database of residents served by the Emilia-Romagna, Italy health service in the years 2004-2012 including demographic information and utilization of health services by 3,726,380 people age ≥ 18 years.

Outcome measures: Models designed to predict risk of hospitalization or death for problems that are potentially avoidable were developed and evaluated using the area under the receiver operating curve C-statistic, in terms of their sensitivity, specificity, and positive predictive value, and for calibration to assess performance across levels of predicted risk.

Results: Among the 3,726,380 adult residents of Emilia-Romagna at the end of 2011, 449,163 (12.1%) were hospitalized in 2012; 4.2% were hospitalized for the selected conditions or died in 2012 (3.6% hospitalized, 1.3% died). The C-statistic for the model predicting 2012 outcomes was 0.856. The model was well calibrated across categories of predicted risk. For those patients in the highest predicted risk decile group, the average predicted risk was 23.9% and the actual prevalence of hospitalization or death was 24.2%.

Conclusions: We have developed a population-based model using a longitudinal administrative database that identifies the risk of hospitalization for residents of the Emilia-Romagna region

1
2
3 with a level of performance as high as, or higher than, similar models. The results of this
4
5 model, along with profiles of patients identified as high risk are being provided to the physicians
6
7 and other health care professionals associated with the Patient Centered Medical Homes to aid in
8
9 planning for care management and interventions that may reduce their patients' likelihood of a
10
11 preventable, high-cost hospitalization.
12
13

14 15 16 17 18 **Strengths and Limitations of this study:** 19

- 20
21 • This study included the entire adult population of the Emilia-Romagna ~~regon~~ Region of
22 Italy, over 3.7 million people.
- 23
24 • The study used an existing longitudinal administrative health care database with both the
25 advantage of much lower cost than new data collection and the disadvantage of potential
26 errors in administrative data.
- 27
28 • The results of the study are being used to assist in the development of newly formed
29 Patient Centered Medical Homes.

Introduction

The predominant healthcare delivery system, which has been a passive model, reacting to patients' problems, is shifting to a more proactive model designed to take the initiative in providing care for an increasingly older population that has a greater prevalence of chronic conditions, often with multiple medical and social needs. These changes are driving the reorganization of the primary care system, emphasizing coordination and cooperation among healthcare professionals.¹ Among the approaches to addressing this need has been the establishment of primary care organizations incorporating integrated teams of physicians and other healthcare professionals that “seek to increase the influence of primary care professionals, and in particular general practitioners (GPs), in health planning and resource allocation.”² Prominent among these new models of primary care is the Patient Centered Medical Home, an organization in which a team of healthcare providers is engaged in delivering comprehensive, coordinated, patient-centered care to patient defined populations.³

Primary care has a central role in the Italian National Health Service (NHS). Twenty one regional governments are responsible for ensuring the delivery of a health benefits package through a network of geographically defined, population-based Local Health Authorities. Primary care physicians work for these authorities as independent contractors and act as “gatekeepers” for specialty and other referral services for their patients.⁴

With the belief that a strong primary care system is conducive to improving population health, the NHS initiated reforms that encouraged primary care physicians to organize into collaborative arrangements. To this end, the Regione Emilia-Romagna (RER), a large northern region with a population of about 4.5 million, has recently launched a plan in its 11 Local Health Authorities to

1
2
3 establish Patient-Centered Medical Homes to better coordinate patient care and help patients
4
5 avoid unnecessary hospitalizations.
6
7

8
9 The identification of those patients who would benefit most from outreach efforts is fundamental
10
11 to achieving these goals of promoting and practicing population health in Patient-Centered
12
13 Medical Homes. To accomplish this, predictive models and risk stratification tools are needed to
14
15 identify patients at risk of a worsening of their health status. According to Knutson and Bella,⁵
16
17 “Predictive models are data-driven, decision-support tools that estimate an individual’s future
18
19 potential health care costs and/or opportunities for care management.” A good model will
20
21 identify as many of these patients as possible while excluding those for whom these interventions
22
23 would be unnecessary or ineffective.
24
25
26
27

28
29 The RER has established three objectives for this project: 1) develop predictive models to
30
31 identify patients at high risk of ~~a progression of their medical problems or who are at risk of~~
32
33 ~~developing new medical problems~~ hospitalization or death, 2) create “risk of hospitalization”
34
35 patient profiles that provide information about their high-risk patients to the general practitioners
36
37 in the newly formed Patient-Centered Medical Homes, and 3) assess the extent to which these
38
39 models and reports provide additional information useful in the identification of patients who
40
41 may benefit from case management or disease management.
42
43
44
45

46 This paper will address the first of the three goals. We describe the development of a predictive
47
48 model using the RER’s regional longitudinal administrative health care database to help identify
49
50 patients who are most at risk of hospitalization for conditions that may be impacted through
51
52 improved patient care. This model will then be used to inform the providers associated with the
53
54 Patient-Centered Medical Homes and aid in their planning for care management and
55
56

1
2
3 interventions that can reduce their patients' likelihood of a preventable, high-cost hospitalization.
4
5
6
7

8 Methods

9 Study Data and Study Population

10
11
12
13
14 The model was developed using the population-based longitudinal health care database of the
15 residents served by the RER Health Service in the years 2004 through 2012.⁶ This
16 administrative database includes demographic information for all residents (gender, birth and
17 death dates, location of current residence, and primary care physician), hospital discharge
18 abstract data (ICD-9-CM diagnosis and procedure codes, and admission and discharge dates),
19 emergency room utilization information, outpatient pharmacy data at the individual prescription
20 level, specialty care (laboratory, diagnostics, therapeutic procedures, rehabilitation, and specialist
21 visits), home health data, and information on each primary care physician in the region. Each
22 patient has an anonymous identifier assigned by the RER so that an individual's utilization can
23 be tracked over time without jeopardizing patient privacy.
24
25
26
27
28
29
30
31
32
33
34
35
36
37

38 The study population consisted of all residents of the RER who were at least 18 years of age and
39 still alive as of 31st December 2011.
40
41
42
43
44
45

46 Dependent Variable

47
48
49 The dependent variable was defined as the occurrence of a hospitalization for problems that are
50 potentially avoidable, or whose progression may have been avoided or delayed through
51 appropriate patient care, or the death of the individual, either in or out of the hospital, for any
52

60

reason in 2012. We decided to not limit the hospitalization to emergency admissions, since a planned admission may also be an indicator of a worsening medical problem. In order to operationally define the dependent variable, we ([authors JSG and DZL](#)) reviewed the Disease Staging^{7, 8} primary diagnostic category and severity stage of all day and inpatient hospital admissions (for adults age 18+) in RER for one year, to select those admissions that should be included in the dependent variable.

Deliveries, admission for dental diseases or admissions for vague signs or symptoms with no identified etiology were excluded. Admissions for problems that are not predictable/preventable were excluded while those where screening may identify problems that can potentially be treated to avoid progression were included. For example, admissions for stage 1, chronic cholecystitis or cholelithiasis were excluded, but admissions for advanced stage 2 or 3 complications such as ascending cholangitis or pancreatitis were included.

We felt that inclusion of hospitalization for cancer in the dependent variable should depend on the ability to either prevent or avoid progression of the disease. We therefore included colon cancer and cervical cancer in the definition because they are potentially preventable but excluded all other cancers where prevention/prediction is not currently possible.

Inclusion of injuries, burns, or toxic reaction to prescription or non-prescription drugs would ideally be based on the cause of these problems. Since the etiology of these problems is typically not available in the administrative data being used in this project, we made the decision to include or exclude based on our subjective judgment of the likelihood of preventability. For example, adverse drug reactions were included but burns were excluded from the definition of the dependent variable.

1
2
3 There is no obvious medical reason for a hospital admission for patients with stage 1 diabetes
4 mellitus or stage 1 essential hypertension without complications. These problems are typically
5 treatable in the outpatient setting. A hospitalization implies a potential problem in the care of
6 these patients, so we decided to include these admissions as a part of the dependent variable.⁹
7
8
9
10
11
12

13 14 15 16 17 18 Independent Variables 19

20 A broad range of candidate predictor variables was developed taking advantage of the RER
21 administrative data. The independent variables used for modeling were defined from the RER
22 administrative data for the years 2004 through 2011. Demographic data included patient age,
23 sex, and geographic location of residence. We developed a mapping to broad disease categories
24 defined primarily in terms of the affected body system from home health care data, pharmacy
25 data, and hospital discharge abstract data. (See Appendix [1](#).)
26
27
28
29
30
31
32
33
34
35
36

37 For those patients who had been hospitalized, more specific diagnostic data were available. We
38 reviewed the classification of patients hospitalized historically using the Disease Staging
39 diagnostic category and disease severity stages.^{7,8} Based on the frequencies specific diagnostic
40 category/stage predictor variables were defined for either specific stages of frequent diseases, or
41 by combinations across similar categories. Predictor variables were defined based on the number
42 of emergency room visits using the RER classifications system for the urgency of the visit.
43
44
45
46
47
48
49
50
51
52

53 Pharmacy data were used to identify polypharmacy¹⁰ (defined as the simultaneous use of five or
54 more active ingredients for at least 15 consecutive days), potential drug-drug interactions
55
56
57
58
59
60

1
2
3 (DDI)¹¹ and potentially inappropriate medication use in patients¹² 65 years and older. Since
4
5 cardiovascular disease is highly prevalent, we reviewed the use of cardiovascular drugs and
6
7 created a variable for each of the following 11 classes of drugs (oral anti-coagulants, beta-
8
9 blockers, angiotensin converting enzyme / angiotensin II receptor blockers, anti-platelets,
10
11 calcium channel blockers, anti-arrhythmics, digitalis glycosides, nitrates, diuretics, alfa-blockers,
12
13 statins) to account for the complexity of therapeutic regimen at the patient level.
14
15
16

17
18
19 To take advantage of the fact that the RER database includes multiple years of data, we created
20
21 history variables using the utilization for each year of data available. Since we were working
22
23 with the 2011 data to predict hospitalization or death in 2012, we created history variables based
24
25 on 2004-2010 data. This set included 83 of the diagnostic category/stage variables as well as 11
26
27 variables based on pharmacy utilization such as exposure to polypharmacy and use of
28
29 cardiovascular drugs. If the individual had a history of a disease in any of the years from 2004 to
30
31 2010 they were flagged as having a history of that disease and this was used as a potential
32
33 predictor variable.
34
35
36
37
38
39
40

41 Modeling

42
43
44 Logistic regression models were used to estimate predicted probabilities for the occurrence of an
45
46 inpatient hospital stay for the selected conditions or death for individual patients. Risk of
47
48 hospitalization or death, and the variables that relate to those risks are highly dependent on age
49
50 and gender. Regression models were fit in each of 14 gender and age strata using SAS Version
51
52 9.2 (SAS Institute, Cary NC). A stepwise process with relaxed covariate entry and retention
53
54 criteria (inclusion p-value ≤ 0.8 , retention ≤ 0.5) was used. At each step in this process, an
55
56
57
58
59
60

1
2
3 attempt is made to remove any unimportant variables from the model before adding a potentially
4 important variable. Each addition or deletion of a variable to or from a potential model is a
5 separate step and, at each step, a new model is fitted. This process results in a ~~for selecting a~~
6 reduced, but robust set of independent variables that predict outcome or that might have
7 importance as adjustment terms for the model in each age/gender stratum.
8
9
10
11
12
13
14
15
16
17
18
19

20 Evaluation of the Models

21
22 The predictive accuracy of the modelling was evaluated using C-statistics (the area under the
23 receiver operating characteristics curve), along with three measures traditionally used with
24 clinical screening tools: sensitivity, specificity and positive predictive value.
25
26
27
28
29

30 C-statistics were used to evaluate the models in two ways. The first evaluation consisted of
31 fitting the model developed using utilization and demographic data from 2011, along with
32 historical variables based on 2004-2010 data, and outcomes (hospitalization or death) from 2012
33 and then computing a C-statistic to evaluate how the models performed at predicting those
34 outcomes on which the models were conditioned. However, this evaluation is not consistent with
35 evaluating how the data are used in practice. In practice, we have current predictor information,
36 but the outcomes have not been realized. To better estimate how the models are likely to perform
37 in this setting, we fit models to outcomes data up to a year prior to the most current available
38 (e.g., 2011 outcomes modelled with predictors from 2010, along with historical variables based
39 on 2004-2009 data). We then computed a C-statistic for projections made on the risk of
40 hospitalization or death outcomes (in 2012) using the next year's predictor information (in 2011).
41
42
43
44
45
46
47
48
49
50
51
52
53
54
55
56 This way, the models are forced to make projections into the future, but we have the actual
57
58
59
60

1
2
3 observed outcomes data to evaluate the modelling process as it would be used in practice. The
4
5 resulting C-statistics obtained from these two model runs were compared.
6
7

8
9 In order to evaluate the performance of the model across different risk thresholds we classified
10
11 predicted risk scores. “Very high risk” was defined as patients with a predicted risk of
12
13 hospitalization or death in the following year of $\geq 25\%$ while “high risk” was defined as patients
14
15 with a predicted risk of hospitalization of 15-24%. These risk thresholds were selected after
16
17 consultation with physicians practicing in the medical homes to yield a total of about 10% of the
18
19 1,500 patients enrolled with a typical primary care physician.
20
21

22 23 **Results**

24
25
26
27 Among the 3,726,380 adult residents of Emilia Romagna at the end of 2011, 449,163 (12.1%)
28
29 were hospitalized in 2012; 4.2% were hospitalized for the selected conditions defined earlier or
30
31 died in 2012 (3.6% hospitalized, 1.3% died).
32
33

34
35 Table 1 shows the distribution of the demographics (age and gender), number of chronic
36
37 conditions, body systems impacted by the selected chronic conditions, polypharmacy and
38
39 inappropriate prescribing among the eligible RER residents, as of December 31, 2011. The
40
41 table also compares these characteristics of the total adult population of the region to the
42
43 subgroups of the population classified in the “very high risk” and “high risk” categories. Based
44
45 on the model results, 114,255 individuals were identified as having a predicted risk of
46
47 hospitalization or death in 2012 of $\geq 25\%$ and classified as “very high risk.” An additional
48
49 134,610 individuals had a predicted risk of hospitalization or death in 2012 of 15-24% and were
50
51 classified as “high risk.”

Any potentially inappropriate medications (age 65 years or older)^{^^}	257,033	25.5%	51,055	48.7%	49,003	39.2%

* Adults (age 18 or older) and alive at 31 December 2011.

** “Very high risk” was defined as patients with a predicted risk of hospitalization or death in the following year of $\geq 25\%$ while “high risk” was defined as patients with a predicted risk of hospitalization of 15-24%.

Men only.

Women only.

[^] Polypharmacy is defined as the simultaneous use of five or more active ingredients for at least 15 consecutive days.

^{^^} The list of potentially inappropriate medications can be found in: Maio V, Del Canale S, Abouzaid S. Using Explicit Criteria to Evaluate the Quality of Prescribing in Elderly Italian Outpatients: A Cohort Study. *Journal of Clinical Pharmacy and Therapeutics* 2010;35:219-229.

There was little difference across the risk categories by gender. Age distributions for the “very high risk” and “high risk” groups were shifted more towards the older age groups than those in the overall study population. Residents age 85 or older represented about 4.5% of the RER population, but about 50% of the “very high” and “high” predicted risk groups. More than 75% of the residents over age 85 were classified as “very ~~high~~” or “high” risk. However, age alone was not sufficient to their predict risk. For example, residents between 75 and 84 years of age made up 23% of the “very high” risk group and 41% of the “high” risk group, but over 85% of the residents in this age category had neither “very high” nor “high” predicted risk.

Across age and gender strata, demographics and health care utilization experience in 2011 were the most commonly used independent variables for predicting hospitalization or death in 2012. Selected history variables flagging chronic problems such as cardiovascular disease, diabetes

1
2
3 mellitus and chronic renal failure and a history of prescriptions for cardiovascular medications
4
5 and polypharmacy were also significant predictors.
6
7

8
9 The residents in the two higher risk groups were more likely than others to have multiple chronic
10
11 diseases and to experience polypharmacy and inappropriate medication use. The residents
12
13 identified as “very high risk” or “high risk” by the model also showed a number of striking
14
15 differences from others in terms of the occurrence of some of the most prevalent health
16
17 conditions by type and body system. Although cardiovascular conditions were not uncommon in
18
19 the total adult population (26.0%), they were far more common among those classified as “very
20
21 high risk” and “high risk” (84.2% and 77.1%, respectively). Similarly, gastrointestinal conditions
22
23 affected 15.6% of the total population, but were diagnosed in 65.4% of the “very high risk” and
24
25 49.3% of the “high risk” patients. Cancer occurred in 2.7% of the total population, but 20.9% of
26
27 the “very high risk” and 10.6% of the “high risk” patients had a cancer diagnosis. Mental health
28
29 problems were identified in 7.8% of the adult population, but in 34.2% of the “very high risk”
30
31 and 25.0% of the “high risk” patients.
32
33
34
35
36
37

38 The C-statistic for the model of 2012 outcomes developed using 2011 predictors and the
39
40 C-statistic based on the parameters from the model of 2011 outcomes regressed on 2010
41
42 predictors applied to the 2011 predictors and 2012 ~~outcomes~~outcomes were very similar (0.856
43
44 and 0.853, respectively). These results suggest that the relationship between predictors and risk
45
46 of hospitalization changed little in one year and that model parameters developed in a prior year
47
48 can be used reliably with the most current year’s data to predict unknown outcomes in the next
49
50 year with only a minimal loss in performance in this population.
51
52
53
54
55
56
57
58
59
60

Table 2 shows the sensitivity, specificity, positive predictive value and number of true positives for the model at the two selected cut-off points. The sensitivity (percentage of patients actually hospitalized who had been identified by the model as having a predicted risk higher than the cut-off point) was 29.8% for those with the “very high” risk scores. This percentage represents 46,950 of the 157,550 residents of the region who were hospitalized for a selected condition or died in 2012. If we modify the risk score threshold to include individuals with a predicted risk of hospitalization for selected conditions or death of $\geq 15\%$ (i.e., both the “very high risk” and the “high risk” patients) the sensitivity is .471. The true negative rate (specificity) is very high for both risk thresholds (.981 and .951, respectively).

Table 2. Performance of the "Risk of Hospitalization" model for residents identified as "Very High Risk" and "High or Very High Risk"		
Measure	Cut-off points for comparison	
	"Very high risk"*	"Very high risk"* + "High risk"**
Sensitivity ^{3#}	0.298	0.471
Specificity ^{4##}	0.981	0.951
Positive Predictive Value ^{5^}	0.411	0.298
True positives ^{6^^}	46,950	74,196
* "Very high risk" is defined as patients with a predicted risk of hospitalization of $\geq 25\%$. ** "Very high risk" + "High risk", is defined as patients with a predicted risk of hospitalization of $\geq 15\%$. # Sensitivity is defined as the proportion of those hospitalized who were predicted to be hospitalized (true positive rate). ## Specificity is the proportion of those not hospitalized who were not predicted to be hospitalized (true negative rate). ^ Positive Predictive Value is the proportion of those predicted to be hospitalized who were actually hospitalized. ^^ True positives are the number of residents who were predicted to be at risk for hospitalization at the predicted risk threshold and were actually hospitalized.		

1
2
3 The model appears to be well calibrated across levels of risk. The Figure depicts the RER
4
5 population divided into groups by deciles of predicted risk of hospitalization or death from the
6
7 models. The observed prevalence of hospitalization or death is compared to the average
8
9 predicted risk among individuals in each of the ten predicted risk groups. For example, the
10
11 overall rate of hospitalization for the selected conditions or death in 2012 was 4.2%. For those
12
13 patients in the highest predicted risk decile group, the average predicted risk was 23.9% and the
14
15 actual prevalence of hospitalization or death was 24.2%. ([Regression coefficients and](#)

31
32
33
34
35

36 **Discussion**

37
38 We have developed a population-based model that identifies the risk of hospitalization for all
39
40 adult RER residents and does so with a level of performance ($c=0.85$) as high as, or higher than,
41
42 similar models. In addition, we believe that the definition of the dependent variable chosen for
43
44 our models increases the probability that they are identifying patients who risk can potentially be
45
46 improved by appropriate care. A systematic review by Kansagara¹³ of models designed to
47
48 predict readmissions, showed C-statistic results in the range of 0.55 to 0.83. Recent work by
49
50 Billings et al¹⁴ to develop models predictive of emergent admissions in the UK had results
51
52 ranging from 0.73 to 0.78. Li Wang, et al. (2013),¹⁵ using information available through the US
53
54
55
56
57
58
59
60

1
2
3 Veteran's Administration that also included lab data, demonstrated c-statistics of 0.81 and 0.79,
4
5 respectively, for their models of 90-day or 12-month hospitalization or death outcomes. At a
6
7 predicted risk of >25% our model had a Positive Predictive Value (PPV) of .411. Billings et al¹⁴
8
9 reported a PPV of .417 at a risk threshold of 30. There is a trade-off in using our model, or any
10
11 predictive model, between the threshold for follow-up and predictive accuracy. A lower risk
12
13 threshold would identify more patients but with a lower prevalence of hospitalization or death.
14
15
16
17

18 Although previous studies have developed models predictive of hospital care, these models fall
19
20 short of the needs of the Patient Centered Medical Homes being implemented in RER. Typically,
21
22 these models have focused on specific age groups,¹⁶ conditions, or types of admissions, such as
23
24 emergent¹⁴ or unplanned admissions or rehospitalizations, or health insurance plans in the United
25
26 States, including private insurance plans, Medicare and Medicaid plans.^{17,18} The models we have
27
28 developed are applied to the entire adult population of RER. They use existing administrative
29
30 data, which makes them cost effective to apply.
31
32
33
34
35

36 Patient Centered Medical Homes, including those instituted in RER, are responsible for
37
38 addressing the needs of their population and making the best use of their finite resources to
39
40 accomplish this. Preventing unnecessary admissions could improve both the quality of care and
41
42 health status of the enrolled population, and result in a substantial savings. To accomplish this,
43
44 predictive models and risk stratification tools such as those developed for this project are needed
45
46 to identify patients at risk of preventable admissions and provide information that can be used by
47
48 the medical homes to help manage care.
49
50
51
52

53 There are some limitations to the model. The model is developed from administrative data.

54 Administrative data are collected for reimbursement and tracking utilization and not for medical
55
56
57
58
59
60

1
2
3 research. They lack the clinical specificity that would be desirable in assessing an individual's
4
5 medical problems. While the hospital discharge abstract data do include diagnostic information
6
7 coded using ICD-9-CM, no similar data are available for outpatient encounters in the RER
8
9
10 database. The mortality data available for this project did not include information about cause
11
12 of death. Therefore, some proportion of patients whose death was not predictable were included,
13
14 limiting model performance. In addition, our models use prior utilization among the predictor
15
16 variables. With the administrative data we cannot distinguish between appropriate and
17
18 inappropriate treatment which may bias our results.
19

20
21
22 Despite the limitations of administrative data, they have many advantages for this project: they
23
24 are readily available, relatively inexpensive to analyze and cover large populations over many
25
26 years. They are ideal for uncovering patterns of care. If information from the medical records is
27
28 needed, the results of these analyses can then be supplemented by focused clinical reviews at the
29
30 local level. Also, The RER has a system in place to monitor the quality of diagnosis and
31
32 procedure coding in their hospital discharge abstract data. Controls at both the hospital and
33
34 regional level assess the validity of coding and the consistency of codes assigned such as
35
36 congruity between sex, age and diagnosis and between diagnosis and procedure. The existence
37
38 of the RER administrative database made it feasible to develop the models described in this
39
40 article at relatively low cost and to update the models over time without additional data
41
42 collection that others have found necessary.¹⁴
43
44
45
46
47
48

49
50 Currently, these risk scores are being integrated with other information in profiles of high-risk
51
52 patients furnished to providers in 12 newly formed medical homes, including 83 primary care
53
54 physicians serving a total of about 100,000 patients, in the Parma Local Health Authority located
55
56

1
2
3 in RER. Along with the risk scores, this information includes data about previous
4
5 hospitalizations, use of referrals, medications, long-term care and home care services, and a
6
7 number of process-like quality indicators for diabetic and cardiovascular patients, and for
8
9 appropriate medication use in older patients.
10

11
12
13 Of course, model results need to lead to an effective intervention to have a positive impact on
14
15 patient care. To this end, we are working with the physicians, nurses, and other health care
16
17 professionals as well as the administration of the newly formed Medical Homes in Parma to
18
19 assist them in understanding how to use the results of these models and in developing potentially
20
21 effective interventions. The individual profiles of high risk patients provided to the health care
22
23 team in the Medical Homes allow them to trigger specific actions such as inviting patients to
24
25 enroll in disease management programs for chronic problems such as heart failure, chronic
26
27 obstructive pulmonary disease, or diabetes mellitus, activating home health assistance, initiating
28
29 a medication review, or recommending that the patient come in for an office visit. An evaluation
30
31 of the use and usefulness of these profiles and intervention is under way.
32
33
34
35
36
37

38 In summary, these models provide a means of identifying patients at high risk for hospitalization.
39
40 The risk predictions, in conjunction with the risk profile, show promise as a useful organizational
41
42 tool for the regional Patient Centered Medical Homes to develop and implement proactive case
43
44 management and disease management programs. The RER is reviewing the results of the Parma
45
46 Local Health Authority pilot project of the profiles. Once their usefulness has been further
47
48 evaluated, their use will be expanded to other Medical Homes in development in the other Local
49
50 Health Authorities in the Emilia-Romagna region. If similar data are available, these models can

Figure Legend:

Figure. Model calibration: Predicted risk and observed prevalence of hospitalization or death in 2012 by predicted risk decile groups.

Contributorship statement: DZL, RG, VM, and JSG were responsible for the conceptualization of this project. MR, JM, and ML were responsible for creation of the datasets used in this project. DZL, VM, MR, and JSG were responsible for the definition of analytical variables. SWK, MR, ML and JM were responsible for modeling and statistical analysis. DZL managed the research team. RG and JSG advised on the analyses and results. All authors contributed to the preparation of the manuscript.

Competing interests: All authors have completed the Unified Competing Interest form and declare grants from the Regione Emilia-Romagna (Louis, Robeson, McAna, Maio, Keith, Liu, Gonnella) during the conduct of the study. Louis and Gonnella declare personal fees from Truven Health Analytics, The National School of Public Health, Portugal, INSIEL Mercato.

Funding: This research was funded by the Agenzia Sanitaria e Sociale of the Emilia-Romagna Region, Italy. The resulting models are being used by the Local Health Authority of Parma, Italy and the Patient Centered Medical Homes located in the Parma Local Health Authority.

Data Sharing: No additional data available.

Appendix 1: Mapping to Body System or Etiology Groups

Body System or Etiology Group	Hospital Discharge data	Outpatient pharmacy data	Home health care	Specialty visits
Cancer	Neoplasm, Malignant: Cardiovascular, Hypopharynx, Oral Cavity, Oropharynx, Salivary Glands and Mandible, Other Endocrine System, Larynx, Glottis, Larynx, Subglottic, Larynx, Supraglottic, Nasopharyngeal, Sinuses, Ocular Melanoma, Other Eye and Periocular, Colon and Rectum, Esophagus, Small Bowel, Stomach, Other Gastrointestinal System, Bladder, Urinary, Kidneys, Other Genitourinary System, Breast (Female), Cervix Uteri, Endometrium, Ovaries, Vagina, Vulva, Other Female Genitalia, Hodgkin's Lymphoma, Multiple Myeloma, Mastocytosis, Pancreas, Other Hepatobiliary Tract, Breast (Male), Penile, Prostate, Testicular, Primary Bone, Waldenstrom's Macroglobulinemia, Nonspecific Sites, Unspecified Primary Site, Lungs, Bronchi, or Mediastinum, Hodgkin's Disease Lymphocytic Depletion, Hodgkin's Disease Lymphocytic Predominance, Hodgkin's Disease Mixed Cellularity, Hodgkin's Disease Nodular Sclerosis, Lymphatic and Hematopoietic (Other Types), Lymphoma, Cutaneous T Cell (Mycosis Fungoides), Lymphoma (Diffuse Mixed Small and Large Cell), Lymphoma (Diffuse Large Cell), Lymphoma (Follicular Predominantly Large Cell), Lymphoma (Histiocytic Cell), Lymphoma (Lymphoblastic), Other Respiratory System, Carcinoma (Basal Cell stage 2/3), Carcinoma (Squamous Cell), Melanoma, Other Skin and Soft	Antineoplastics 5HT3 Antagonists	2005-2009: Visits prescribed due to the presence of cancer. Beginning in 2010, the following ICD-9-CM codes were in the record: 140-208, 235-239, V10, V16	Visits prescribed for radiation therapy, or for Injection or infusion of chemotherapeutic Substances for cancer treatment

A-1

Body System or Etiology Group	Hospital Discharge data	Outpatient pharmacy data	Home health care	Specialty visits
	Tissue Neoplasm: Pheochromocytoma, Eyelid, Central Nervous System, Lymphatic or Hematopoietic Leukemia: Acute Lymphocytic, Acute Nonlymphocytic, Chronic Lymphocytic, Chronic Myelogenous, Other Types Encounter for: Chemotherapy, Radiation Therapy ICD-9-CM Procedure codes: 99.25, 99.28, 00.10,00.15,92.2x			
Cardiovascular	Aneurysm: Abdominal, Thoracic Anomaly: Patent Ductus Arteriosus, Atrial Septal Defect, Atrioventricular Defects, Coarctation of the Aorta, Other Congenital Heart Disease, Pulmonary Valve Stenosis, Tetralogy of Fallot (stage 3), Transposition of the Great Arteries, Ventricular Septal Defects, Other Circulatory System Aortic: Regurgitation, Stenosis Mitral: Regurgitation, Stenosis Neoplasm: Benign of the Cardiovascular System Arrhythmias, Cardiomyopathies, Conduction Disorders, Congestive Heart Failure, Coronary Artery Disease Prior Coronary Revascularization, Coronary Artery Disease w/o Prior, Coronary Revascularization, Essential Hypertension, Infective, Endocarditis, Pericarditis: Chronic (stage 2/3), Viral or Traumatic (stage 2/3) Periarteritis Nodosa, Raynaud's Disease, Thromboangiitis,	Oral anti-coagulants beta-blockers ACE/ARB anti-platelets calcium channel blockers anti-arrhythmics digitalis glycosides nitrates diuretics alfa-blockers statins	2005-2009: Visits prescribed due to the presence of Congestive Heart Failure or not-well defined cardiopathy, and other diseases of cardiovascular system. Beginning in 2010, the following ICD- 9-CM-CM codes were in the record: 390-454,456-459

Body System or Etiology Group	Hospital Discharge data	Outpatient pharmacy data	Home health care	Specialty visits
	Obliterans, Thrombophlebitis, Tibial, Iliac, Femoral, or Popliteal Artery Disease, Varicose Veins of Lower Extremities, Secondary Hypertension, Budd Chiari Syndrome, Rheumatic Fever (stage 2/3) Vasculitis Other: Atherosclerosis, Cardiac Conditions, Cardiovascular Symptoms, Circulatory Disorders, Diseases of Arteries, Diseases of Veins, Disorders of Pulmonary Circulation, Lymphatic Disorders			
Endocrine	Adrenal Insufficiency, Cushing's Syndrome, Diabetes insipidus, Diabetes Mellitus Type 1, Diabetes Mellitus Type 2 and Hyperglycemic States,Hyperthyroidism, Hypoglycemia, Hypothyroidism, Monotropic Hormone Deficiency, Primary Amyloidosis, Thyroiditis, Klinefelter's Syndrome, Turner's or Noonan's Syndrome, Obesity Goiter: Nontoxic or Euthyroid (stage 2/3) Neoplasm, Benign: Acromegaly, Adenoma, Parathyroid, Hyperparathyroidism, Primary Hyperaldosteronism, Other Endocrine System Neoplasm, Malignant:Thyroid Other: Endocrine Disorders, Electrolyte Disorders, Nutritional and Metabolic Disorders Anomaly: Adrenal Hyperplasia	Insulins biguanides sulfonylureas vasopressin thyroid replacement antithyroid agents	2005-2009: Visits prescribed due to the presence of diabetes mellitus Beginning in 2010, the following ICD-9-CM codes were in the record: 240-278	

Body System or Etiology Group	Hospital Discharge data	Outpatient pharmacy data	Home health care	Specialty visits
Ear, Nose, Throat	Diseases of Salivary Gland, Incl. Parotitis or Benign Tumors, Other Disorders of Oral Cavity (stage 2), Cholesteatoma, Meniere's Disease, Otitis Media, Sinusitis Hearing Loss due to: Acoustic Trauma, Otosclerosis Neoplasm, Benign: Larynx, Sinuses, Oral Cavity and Pharyngeal Structures Pharyngitis: Non-Streptococcal (stage 2)			
Eye	Cataract, Conjunctivitis: Bacterial, Contusion or Ruptured Globe, Dacryostenosis or Dacryocystitis, Detachment of the Retina, Ectropion or Entropion (Abnormal Lower Lid Position), Endophthalmitis, Foreign Body: Orbit, Fracture: Orbit, Blow-Out, Fungal Infection of the Eye, Glaucoma, Hypovitaminosis A, Laceration: Cornea, Macular Degeneration, Orbital Infection, Prematurity: Retinopathy, Ptosis of Upper Lid, Retrobulbar Orbital Hemorrhage, Trachoma, Other Eye Disorders Injury or Laceration: Eyelid, Periocular, Cornea, Conjunctiv Injury: Eyes, Nonionizing Radiation Keratitis: Acanthamoeba, Bacterial Neoplasm, Benign: Eye	Sympaticomimetic agents parasympaticomimetic agents anhydrase inhibitors ophthalmic beta blockers		
Gastrointestinal	Anorectal Suppuration, Celiac Disease, Clostridium difficile Colitis, Crohn's Disease, Diverticular Disease, Food Poisoning: Other Organisms (stage 3), Functional Digestive Disorders, Gastritis, Hemorrhoids, Hernia (External), Hernia (Hiatal or Reflux Esophagitis), Intussusception (stage 2), Irritable Bowel Syndrome, Gastroenteritis	Intestinal corticosteroids agents H2 antagonists prostaglandins proton pump inhibitors	2005-2009: Visits prescribed due to the presence of Gastrointestinal Diseases Beginning in 2010,

Body System or Etiology Group	Hospital Discharge data	Outpatient pharmacy data	Home health care	Specialty visits
	Neoplasm, Benign: Adenomatous Polyps, Colon, Small Bowel, Other Gastrointestinal System Peptic Ulcer Disease, Salmonellosis (stage 3), Ulcerative Colitis, Vascular Insufficiency of the Bowels, Complications of Gastrointestinal Treatment, Gastroenteritis (stage 2/3) Other Diseases of Esophagus, Stomach, and Duodenum Other Gastrointestinal Disorders, Other Gastrointestinal Infections (stage 2), Other Gastrointestinal or Abdominal Symptoms Anomaly: Congenital Megacolon, Other Digestive or Hepatobiliary System Burns, Chemical: Esophagus, Stomach, or Small Intestine, Laceration: Esophagus		the following ICD-9-CM codes were in the record: 520-539,550-579	
Genitourinary	Bladder Disorders, Calculus of the Urinary Tract, Glomerulonephritis, Acute, Injury: Urinary Tract, Nephrotic Syndrome (stage 2/3), Renal Failure (stage 2/3), Urethritis, Urinary Tract Infections, Neoplasm, Benign: Urinary Tract, Other Disorders of Kidney or Ureter, Other Urinary Symptoms, Encounter for Dialysis, Anomaly: Defects of Kidney, Defects of Lower Genitourinary Tract, Syphilis: Congenital	Agents for hyperkalemia and hyperphosphatemia	2005-2009: Visits prescribed due to the presence of renal failure and Other diseases of the genito-urinary system Beginning in 2010, the following ICD-9-CM codes were in the record: 580-629	Visits prescribed for dialysis

Body System or Etiology Group	Hospital Discharge data	Outpatient pharmacy data	Home health care	Specialty visits
Gynecological and Obstetrics	Anomaly: External Female Genitalia, Anomaly: Uterus, Dysfunctional Uterine Bleeding, Endometriosis, Neoplasm, Benign: Ovary (stage 2), Pelvic Inflammatory Disease, Uterine Infection, Uterovaginal Prolapse, Vulvovaginitis, Other Disorders of Female Genital System			
Hematological	Agranulocytosis, Anemia: Aplastic, Acquired (stage 2/3), Folic Acid Deficiency, Hemolytic (stage 2/3), Iron Deficiency, Sickle Cell, Thalassemia, Vitamin B-12 Deficiency, Other Graft versus Host reaction, Hemophilia A or B, Polycythemia Vera, Other Disorders of Blood and Blood-Forming Organs	Iron vitamin B12 folic acids	Beginning in 2010, the following ICD-9-CM codes were in the record: 280-289	
Hepatobiliary	Cholecystitis and Cholelithiasis, Cirrhosis of the Liver (stage 2/3), Disorders of Bilirubin Excretion, Hepatitis A, Hepatitis B, Hepatitis C, Hepatitis D, Hepatitis E, Hepatitis G, Hepatitis (Chemical), Pancreatitis, Wilson's Disease, Neoplasm, Benign: Hepatobiliary System, Other Hepatobiliary and Pancreatic Disorders, Other Hepatobiliary Infections, Other Pancreatic Disorders	Interferons blood substitutes and plasmatic protein fractions		
Immunologic Diseases	Human Immunodeficiency Virus Type I (HIV) Infection, Other Immunodeficient Disorders, Pneumonia: Pneumocystis carinii	Nucleosides and nucleotides reverse transcriptase inhibitors	2005-2009: Visits prescribed due to HIV Infections Beginning in 2010, the following ICD-9-CM codes were in the record: 279

Predicting Risk Using a Population Based Longitudinal Database

Louis et al

STROBE Statement—checklist of items that should be included in reports of observational studies

	Item No	Recommendation	
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	See abstract section: Design.
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	The outcome measures used and what was found are summarized in the sections of the abstract: Main outcome measures and Results
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	See the Introduction section pages 4 and 5
Objectives	3	State specific objectives, including any prespecified hypotheses	Our objectives are described in the last two paragraphs of the Introduction
Methods			
Study design	4	Present key elements of study design early in the paper	See last paragraph of the Introduction and the Methods section
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	See <u>Study Data and Study Population</u> at beginning of Methods section
Participants	6	(a) <i>Cohort study</i> —Give the eligibility criteria, and the sources and methods of selection of participants. Describe methods of follow-up	Our study includes 100% of the adult population See <u>Study Data and Study Population</u> at beginning of Methods section
		(b) <i>Cohort study</i> —Give the eligibility criteria, and the sources and methods of case ascertainment and control selection. Give the rationale for the choice of cases and controls <i>Cross-sectional study</i> —Give the eligibility criteria, and the sources and methods of selection of participants	
		(b) <i>Cohort study</i> —For matched studies, give matching criteria and number of exposed and unexposed	
		<i>Case-control study</i> —For matched studies, give matching criteria and the number of controls per case	
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	See the Dependent variable and Independent variable sections in the Methods section
Data sources/ measurement	8*	For each variable of interest, give sources of data	See the Dependent variable

		and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	and Independent variable sections in the Methods section. In addition we have included an Appendix with detailed mapping to independent variable.
Bias	9	Describe any efforts to address potential sources of bias	See Evaluation of the Models (page 10) in the Methods section
Study size	10	Explain how the study size was arrived at	Our study includes 100% of the adult population
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	See the Dependent variable and Independent variable sections in the Methods section. In addition we have included an Appendix with detailed mapping to independent variable.
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	See the Modelling section and Evaluation of the Models section (pages 9 and 10) of the Methods
		(b) Describe any methods used to examine subgroups and interactions	See the Modelling section (pages 9 and 10) of the Methods
		(c) Explain how missing data were addressed	
		(d) <i>Cohort study</i> —If applicable, explain how loss to follow-up was addressed <i>Case-control study</i> —If applicable, explain how matching of cases and controls was addressed <i>Cross-sectional study</i> —If applicable, describe analytical methods taking account of sampling strategy	Our study includes 100% of the adult population
		(e) Describe any sensitivity analyses	See Evaluation of the Models last paragraph of Methods.
Results			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	See Page 11 Results section
		(b) Give reasons for non-participation at each stage	N/A
		(c) Consider use of a flow diagram	
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	See Table 1 and Results section (page 11-14)
		(b) Indicate number of participants with missing data for each variable of interest	

		(c) <i>Cohort study</i> —Summarise follow-up time (eg, average and total amount)	N/A
Outcome data	15*	<i>Cohort study</i> —Report numbers of outcome events or summary measures over time	
		<i>Case-control study</i> —Report numbers in each exposure category, or summary measures of exposure	
		<i>Cross-sectional study</i> —Report numbers of outcome events or summary measures	See Table 2 and figure and pages 14 and 15 of Results section
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	See pages 13
		(b) Report category boundaries when continuous variables were categorized	
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	See Table 2 and page 13 and 14.
Discussion			
Key results	18	Summarise key results with reference to study objectives	See Discussion section page 16
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	See Discussion section pages 17 and 18
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	See Discussion section page 18
Generalisability	21	Discuss the generalisability (external validity) of the study results	See Discussion section pages 18 and 19
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	The study was funded by the Emilia-Romagna, region of Italy. See page 3.

*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at <http://www.plosmedicine.org/>, Annals of Internal Medicine at <http://www.annals.org/>, and Epidemiology at <http://www.epidem.com/>). Abstract

Objectives: Develop predictive models using an administrative health care database that provide information for Patient Centered Medical Homes to proactively identify patients at risk of hospitalization for conditions that may be impacted through improved patient care.

Design: Retrospective health care utilization analysis with multivariate logistic regression models.

Data: A population-based longitudinal database of residents served by the Emilia-Romagna, Italy health service in the years 2004-2012 including demographic information and utilization of health services by 3,726,380 people age ≥ 18 years.

Outcome measures: Models designed to predict risk of hospitalization or death in 2012 for problems that are potentially avoidable were developed and evaluated using the area under the receiver operating curve C-statistic, in terms of their sensitivity, specificity, and positive predictive value, and for calibration to assess performance across levels of predicted risk.

Results: Among the 3,726,380 adult residents of Emilia-Romagna at the end of 2011, 449,163 (12.1%) were hospitalized in 2012; 4.2% were hospitalized for the selected conditions or died in 2012 (3.6% hospitalized, 1.3% died). The C-statistic for predicting 2012 outcomes was 0.856. The model was well calibrated across categories of predicted risk. For those patients in the highest predicted risk decile group, the average predicted risk was 23.9% and the actual prevalence of hospitalization or death was 24.2%.

Conclusions: We have developed a population-based model using a longitudinal administrative database that identifies the risk of hospitalization for residents of the Emilia-Romagna region

1
2
3 with a level of performance as high as, or higher than, similar models. The results of this
4
5 model, along with profiles of patients identified as high risk are being provided to the physicians
6
7 and other health care professionals associated with the Patient Centered Medical Homes to aid in
8
9 planning for care management and interventions that may reduce their patients' likelihood of a
10
11 preventable, high-cost hospitalization.
12
13

14 15 16 17 18 **Strengths and Limitations of this study:** 19

- 20 • This study included the entire adult population of the Emilia-Romagna Region of Italy,
21 over 3.7 million people.
- 22 • The study used an existing longitudinal administrative health care database with both the
23 advantage of much lower cost than new data collection and the disadvantage of potential
24 errors in administrative data.
- 25 • The results of the study are being used to assist in the development of newly formed
26 Patient Centered Medical Homes.

Introduction

The predominant healthcare delivery system, which has been a passive model, reacting to patients' problems, is shifting to a more proactive model designed to take the initiative in providing care for an increasingly older population that has a greater prevalence of chronic conditions, often with multiple medical and social needs. These changes are driving the reorganization of the primary care system, emphasizing coordination and cooperation among healthcare professionals.^{1,2,3} Among the approaches to addressing this need has been the establishment of Patient Centered Medical Homes, organizations in which teams of healthcare providers are engaged in delivering comprehensive, coordinated, patient-centered care to patient defined populations.

Primary care has a central role in the Italian National Health Service (NHS). Twenty one regional governments are responsible for ensuring the delivery of a health benefits package through a network of geographically defined, population-based Local Health Authorities. Primary care physicians work for these authorities as independent contractors and act as “gatekeepers” for specialty and other referral services for their patients.⁴

With the belief that a strong primary care system is conducive to improving population health, the NHS initiated reforms that encouraged primary care physicians to organize into collaborative arrangements. To this end, the Regione Emilia-Romagna (RER), a large northern region with a population of about 4.5 million, has recently launched a plan in its 11 Local Health Authorities to establish Patient-Centered Medical Homes to better coordinate patient care and help patients avoid unnecessary hospitalizations.

1
2
3 The identification of those patients who would benefit most from outreach efforts is
4
5 fundamental to achieving these goals of promoting and practicing population health in Patient
6
7 Centered Medical Homes. The RER has established three objectives for this project: 1) develop
8
9 predictive models to identify patients at high risk of hospitalization or death, 2) create “risk of
10
11 hospitalization” patient profiles that provide information about their high-risk patients to the
12
13 general practitioners in the newly formed Patient Centered Medical Homes, and 3) assess the
14
15 extent to which these models and reports provide additional information useful in the
16
17 identification of patients who may benefit from case management or disease management.
18
19
20
21
22

23 This paper will address the first of the three goals. We describe the development of a predictive
24
25 model using the RER’s regional longitudinal administrative health care database to help identify
26
27 patients who are most at risk of hospitalization for conditions that may be impacted through
28
29 improved patient care. This model will then be used to inform the providers associated with the
30
31 Patient Centered Medical Homes and aid in their planning for care management and
32
33 interventions that can reduce their patients’ likelihood of a preventable, high-cost hospitalization.
34
35
36
37
38
39

40 Methods

41 Study Data and Study Population

42
43 The model was developed using the population-based longitudinal health care database of the
44
45 residents served by the RER Health Service in the years 2004 through 2012.⁵ This
46
47 administrative database includes demographic information for all residents (gender, birth and
48
49 death dates, location of current residence, and primary care physician), hospital discharge
50
51 abstract data (ICD-9-CM diagnosis and procedure codes, and admission and discharge dates),
52
53
54
55
56
57

1
2
3 emergency room utilization information, outpatient pharmacy data at the individual prescription
4 level, specialty care (laboratory, diagnostics, therapeutic procedures, rehabilitation, and specialist
5 visits), home health data, and information on each primary care physician in the region. Each
6 patient has an anonymous identifier assigned by the RER so that an individual's utilization can
7 be tracked over time without jeopardizing patient privacy.
8
9

10
11 The study population consisted of all residents of the RER who were at least 18 years of age and
12 still alive as of 31st December 2011. Health care utilization data from 2011 and history variables
13 using data from 2004 through 2010 were used to predict outcomes in 2012.
14
15

16 17 18 19 20 21 22 23 24 25 26 Dependent Variable 27

28
29 The dependent variable was defined as the occurrence of a hospitalization for problems that are
30 potentially avoidable, or whose progression may have been avoided or delayed through
31 appropriate patient care, or the death of the individual, either in or out of the hospital, for any
32 reason in 2012. We included deaths in the dependent variable since we believe that, for
33 example, a patient with coronary artery disease who dies secondary to an acute myocardial
34 infarction, should be included in the dependent variable even if the death is out of the hospital.
35 We decided to not limit the hospitalization to emergency admissions, since a planned admission
36 may also be an indicator of a worsening medical problem. In order to operationally define the
37 dependent variable, we (authors JSG and DZL) reviewed the Disease Staging^{6,7} primary
38 diagnostic category and severity stage of all day and inpatient hospital admissions (for adults age
39 18+) in RER for one year, to select those admissions that should be included in the dependent
40 variable.
41
42
43
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 Admissions to deliver a baby, admission for dental diseases or admissions for vague signs or
4 symptoms with no identified etiology were excluded. Admissions for problems that are not
5 predictable/preventable were excluded while those where screening may identify problems that
6 can potentially be treated to avoid progression were included. For example, admissions for stage
7 1, chronic cholecystitis or cholelithiasis were excluded, but admissions for advanced stage 2 or 3
8 complications such as ascending cholangitis or pancreatitis were included.
9

10
11
12 We felt that inclusion of hospitalization for cancer in the dependent variable should depend on
13 the ability to either prevent or avoid progression of the disease. We therefore included colon
14 cancer and cervical cancer in the definition because they are potentially preventable but excluded
15 all other cancers where prevention/prediction is not currently possible.
16
17

18
19
20 Inclusion of injuries, burns, or toxic reaction to prescription or non-prescription drugs would
21 ideally be based on the cause of these problems. Since the etiology of these problems is typically
22 not available in the administrative data being used in this project, we made the decision to
23 include or exclude based on our subjective judgment of the likelihood of preventability. For
24 example, adverse drug reactions were included but burns were excluded from the definition of
25 the dependent variable.
26
27

28
29
30 There is no obvious medical reason for a hospital admission for patients with stage 1 diabetes
31 mellitus or stage 1 essential hypertension without complications. These problems are typically
32 treatable in the outpatient setting. A hospitalization implies a potential problem in the care of
33 these patients, so we decided to include these admissions as a part of the dependent variable.⁸

Independent Variables

A broad range of candidate predictor variables was developed taking advantage of the RER administrative data. The independent variables used for modeling were defined from the RER administrative data for the years 2004 through 2011. Demographic data included patient age, sex, and geographic location of residence. We developed a mapping to broad disease categories defined primarily in terms of the affected body system from home health care data, pharmacy data, and hospital discharge abstract data. (See Appendix 1.)

For those patients who had been hospitalized, more specific diagnostic data were available. We reviewed the classification of patients hospitalized historically using the Disease Staging diagnostic category and disease severity stages.^{6,7} Based on the frequencies specific diagnostic category/stage predictor variables were defined for either specific stages of frequent diseases, or by combinations across similar categories. Predictor variables were defined based on the number of emergency room visits using the RER classifications system for the urgency of the visit.

Pharmacy data were used to identify polypharmacy⁹ (defined as the simultaneous use of five or more active ingredients for at least 15 consecutive days), potential drug-drug interactions (DDI)¹⁰ and potentially inappropriate medication use in patients¹¹ 65 years and older. Since cardiovascular disease is highly prevalent, we reviewed the use of cardiovascular drugs and created a variable for each of the following 11 classes of drugs (oral anti-coagulants, beta-blockers, angiotensin converting enzyme / angiotensin II receptor blockers, anti-platelets,

4
5 blockers, statins) to account for the complexity of therapeutic regimen at the patient level.
6
7
8
9

10 To take advantage of the fact that the RER database includes multiple years of data, we created
11 history variables using the utilization for each year of data available. Since we were working
12 with the 2011 data to predict hospitalization or death in 2012, we created history variables based
13 on 2004-2010 data. This set included 83 of the diagnostic category/stage variables as well as 11
14 variables based on pharmacy utilization such as exposure to polypharmacy and use of
15 cardiovascular drugs. If the individual had a history of a disease in any of the years from 2004 to
16 2010 they were flagged as having a history of that disease and this was used as a potential
17 predictor variable.

32 Modeling

33
34

35 Logistic regression models were used to estimate predicted probabilities for the occurrence of an
36 inpatient hospital stay for the selected conditions or death for individual patients. Risk of
37 hospitalization or death, and the variables that relate to those risks are highly dependent on age
38 and gender. Regression models were fit in each of 14 gender and age strata using SAS Version
39 9.2 (SAS Institute, Cary NC). A stepwise process with relaxed covariate entry and retention
40 criteria (inclusion p-value ≤ 0.8 , retention ≤ 0.5) was used. At each step in this process, an
41 attempt is made to remove any unimportant variables from the model before adding a potentially
42 important variable. Each addition or deletion of a variable to or from a potential model is a
43 separate step and, at each step, a new model is fitted. This process results in a reduced, but robust

5 terms for the model in each age/gender stratum.
6
7
8
9

10 11 12 Evaluation of the Models 13

14
15 The predictive accuracy of the modelling was evaluated using C-statistics (the area under the
16
17 receiver operating characteristics curve), along with three measures traditionally used with
18
19 clinical screening tools: sensitivity, specificity and positive predictive value.
20
21

22
23 C-statistics were used to evaluate the models in two ways. The first evaluation consisted of
24
25 fitting the model developed using utilization and demographic data from 2011, along with
26
27 historical variables based on 2004-2010 data, and outcomes (hospitalization or death) from 2012
28
29 and then computing a C-statistic to evaluate how the models performed at predicting those
30
31 outcomes on which the models were conditioned. However, this evaluation is not consistent with
32
33 evaluating how the data are used in practice. In practice, we have current predictor information,
34
35 but the outcomes have not been realized. To better estimate how the models are likely to perform
36
37 in this setting, we fit models to outcomes data up to a year prior to the most current available
38
39 (e.g., 2011 outcomes modelled with predictors from 2010, along with historical variables based
40
41 on 2004-2009 data). We then computed a C-statistic for projections made on the risk of
42
43 hospitalization or death outcomes (in 2012) using the next year's predictor information (in 2011).
44
45 This way, the models are forced to make projections into the future, but we have the actual
46
47 observed outcomes data to evaluate the modelling process as it would be used in practice. The
48
49 resulting C-statistics obtained from these two model runs were compared.

58
59
60

In order to evaluate the performance of the model across different risk thresholds we classified predicted risk scores. “Very high risk” was defined as patients with a predicted risk of hospitalization or death in the following year of $\geq 25\%$ while “high risk” was defined as patients with a predicted risk of hospitalization of 15-24%. These risk thresholds were selected after consultation with physicians practicing in the medical homes to yield a total of about 10% of the 1,500 patients enrolled with a typical primary care physician.

Results

Among the 3,726,380 adult residents of Emilia Romagna at the end of 2011, 449,163 (12.1%) were hospitalized in 2012; 4.2% were hospitalized for the selected conditions defined earlier or died in 2012 (3.6% hospitalized, 1.3% died).

Table 1 shows the distribution of the demographics (age and gender), number of chronic conditions, body systems impacted by the selected chronic conditions, polypharmacy and inappropriate prescribing among the eligible RER residents, as of December 31, 2011. Table 1 also compares these characteristics of the total adult population of the region to the subgroups of the population classified in the “very high risk” and “high risk” categories. Based on the model results, 114,255 individuals were identified as having a predicted risk of hospitalization or death in 2012 of $\geq 25\%$ and classified as “very high risk.” An additional 134,610 individuals had a predicted risk of hospitalization or death in 2012 of 15-24% and were classified as “high risk.”

1
2
3 * Adults (age 18 or older) and alive at 31 December 2011.

4 ** "Very high risk" was defined as patients with a predicted risk of hospitalization or death in the following year of
5 $\geq 25\%$ while "high risk" was defined as patients with a predicted risk of hospitalization of 15-24%.

6 # Men only.

7 ## Women only.

8 ^ Polypharmacy is defined as the simultaneous use of five or more active ingredients for at least 15 consecutive
9 days.

10 ^^ The list of potentially inappropriate medications can be found in: Maio V, Del Canale S, Abouzaid S. Using
11 Explicit Criteria to Evaluate the Quality of Prescribing in Elderly Italian Outpatients: A Cohort Study. *Journal of*
12 *Clinical Pharmacy and Therapeutics* 2010;35:219-229.

13
14
15
16
17
18 There was little difference across the risk categories by gender. Age distributions for the "very
19 high risk" and "high risk" groups were shifted more towards the older age groups than those in
20 the overall study population. Residents age 85 or older represented about 4.5% of the RER
21 population, but about 50% of the "very high" and "high" predicted risk groups. More than 75%
22 of the residents over age 85 were classified as "very high" or "high" risk. However, age alone
23 was not sufficient to predict their risk. For example, residents between 75 and 84 years of age
24 made up 23% of the "very high" risk group and 41% of the "high" risk group, but over 85% of
25 the residents in this age category had neither "very high" nor "high" predicted risk.

32
33
34
35
36
37

38 Across age and gender strata, demographics and health care utilization experience in 2011 were
39 the most commonly used independent variables for predicting hospitalization or death in 2012.
40 Selected history variables flagging chronic problems such as cardiovascular disease, diabetes
41 mellitus and chronic renal failure and a history of prescriptions for cardiovascular medications
42 and polypharmacy were also significant predictors.
43
44
45
46
47
48
49
50

51 The residents in the two higher risk groups were more likely than others to have multiple chronic
52 diseases and to experience polypharmacy and inappropriate medication use. The residents
53 identified as "very high risk" or "high risk" by the model also showed a number of striking
54
55
56
57

1
2
3 differences from others in terms of the occurrence of some of the most prevalent health
4 conditions by type and body system. Although cardiovascular conditions were not uncommon in
5 the total adult population (26.0%), they were far more common among those classified as “very
6 high risk” and “high risk” (84.2% and 77.1%, respectively). Similarly, gastrointestinal conditions
7 affected 15.6% of the total population, but were diagnosed in 65.4% of the “very high risk” and
8 49.3% of the “high risk” patients. Cancer occurred in 2.7% of the total population, but 20.9% of
9 the “very high risk” and 10.6% of the “high risk” patients had a cancer diagnosis. Mental health
10 problems were identified in 7.8% of the adult population, but in 34.2% of the “very high risk”
11 and 25.0% of the “high risk” patients.

24
25 The C-statistic for the model of 2012 outcomes developed using 2011 predictors and the
26 C-statistic based on the parameters from the model of 2011 outcomes regressed on 2010
27 predictors applied to the 2011 predictors and 2012 outcomes were very similar (0.856 and 0.853,
28 respectively). These results suggest that the relationship between predictors and risk of
29 hospitalization changed little in one year and that model parameters developed in a prior year can
30 be used reliably with the most current year’s data to predict unknown outcomes in the next year
31 with only a minimal loss in performance in this population.

38
39
40
41
42

43 Table 2 shows the sensitivity, specificity, positive predictive value and number of true positives
44 for the model at the two selected cut-off points. The sensitivity (percentage of patients actually
45 hospitalized who had been identified by the model as having a predicted risk higher than the cut-
46 off point) was 29.8% for those with the “very high” risk scores. This percentage represents
47 46,950 of the 157,550 residents of the region who were hospitalized for a selected condition or
48 died in 2012. If we modify the risk score threshold to include individuals with a predicted risk of
49
50
51
52
53
54
55
56
57
58
59
60

hospitalization for selected conditions or death of $\geq 15\%$ (i.e., both the “very high risk” and the “high risk” patients) the sensitivity is .471. The true negative rate (specificity) is very high for both risk thresholds (.981 and .951, respectively).

Measure	Cut-off points for comparison	
	"Very high risk"*	"Very high risk"* + "High risk"**
Sensitivity[#]	0.298	0.471
Specificity^{##}	0.981	0.951
Positive Predictive Value[^]	0.411	0.298
True positives^{^^}	46,950	74,196

* "Very high risk" is defined as patients with a predicted risk of hospitalization of $\geq 25\%$.
 ** "Very high risk" + "High risk", is defined as patients with a predicted risk of hospitalization of $\geq 15\%$.
 # Sensitivity is defined as the proportion of those hospitalized who were predicted to be hospitalized (true positive rate).
 ## Specificity is the proportion of those not hospitalized who were not predicted to be hospitalized (true negative rate).
 ^ Positive Predictive Value is the proportion of those predicted to be hospitalized who were actually hospitalized.
 ^^ True positives are the number of residents who were predicted to be at risk for hospitalization at the predicted risk threshold and were actually hospitalized.

The model appears to be well calibrated across levels of risk. Figure 1 depicts the RER population divided into groups by deciles of predicted risk of hospitalization or death from the models. The observed prevalence of hospitalization or death is compared to the average predicted risk among individuals in each of the ten predicted risk groups. For example, the overall rate of hospitalization for the selected conditions or death in 2012 was 4.2%. For those patients in the highest predicted risk decile group, the average predicted risk was 23.9% and the actual prevalence of hospitalization or death was 24.2%. (Regression coefficients and

13

14 15 **Discussion** 16

17 We have developed a population-based model that identifies the risk of hospitalization for all
18 adult RER residents and does so with a level of performance ($c=0.85$) as high as, or higher than,
19 similar models. In addition, we believe that the definition of the dependent variable chosen for
20 our models increases the probability that they are identifying patients who risk can potentially be
21 improved by appropriate care. A systematic review by Kansagara¹² of models designed to
22 predict readmissions, showed C-statistic results in the range of 0.55 to 0.83. Recent work by
23 Billings et al¹³ to develop models predictive of emergent admissions in the UK had results
24 ranging from 0.73 to 0.78. Li Wang, et al. (2013),¹⁴ using information available through the
25 United States Department of Veterans Affairs that also included lab data, demonstrated C-
26 statistics of 0.81 and 0.79, respectively, for their models of 90-day or 12-month hospitalization or
27 death outcomes. At a predicted risk of $\geq 25\%$ our model had a Positive Predictive Value (PPV)
28 of .411. Billings et al¹⁴ reported a PPV of .417 at a risk threshold of 30. There is a trade-off in
29 using our model, or any predictive model, between the threshold for follow-up and predictive
30 accuracy. A lower risk threshold would identify more patients but with a lower prevalence of
31 hospitalization or death.

1
2
3 Although previous studies have developed models predictive of hospital care, these models fall
4 short of the needs of the Patient Centered Medical Homes being implemented in RER. Typically,
5 these models have focused on specific age groups,¹⁵ conditions, or types of admissions, such as
6 emergent¹⁴ or unplanned admissions or rehospitalizations, or health insurance plans in the United
7 States, including private insurance plans, Medicare and Medicaid plans.^{16,17} The models we have
8 developed are applied to the entire adult population of RER. They use existing administrative
9 data, which makes them cost effective to apply.
10
11
12
13
14
15
16
17
18
19

20 Patient Centered Medical Homes, including those instituted in RER, are responsible for
21 addressing the needs of their population and making the best use of their finite resources to
22 accomplish this. Preventing unnecessary admissions could improve both the quality of care and
23 health status of the enrolled population, and result in a substantial savings. To accomplish this,
24 predictive models and risk stratification tools such as those developed for this project are needed
25 to identify patients at risk of preventable admissions and provide information that can be used by
26 the medical homes to help manage care.
27
28
29
30
31
32
33
34
35
36

37 There are some limitations to the model. The model is developed from administrative data.
38 Administrative data are collected for reimbursement and tracking utilization and not for medical
39 research. They lack the clinical specificity that would be desirable in assessing an individual's
40 medical problems. Patients with medical problems who have not used the services included in
41 the database cannot be identified. While the hospital discharge abstract data do include
42 diagnostic information coded using ICD-9-CM, no similar data are available for outpatient
43 encounters in the RER database. The mortality data available for this project did not include
44 information about cause of death. Therefore, some proportion of patients whose death was not
45
46
47
48

51
52
53
54
55
56
57
58
59
60

1
2
3 predictable were included, limiting model performance. In addition, our models use prior
4
5 utilization among the predictor variables. With the administrative data we cannot distinguish
6
7 between appropriate and inappropriate treatment which may bias our results.
8
9

10
11 Despite the limitations of administrative data, they have many advantages for this project: they
12
13 are readily available, relatively inexpensive to analyze and cover large populations over many
14
15 years. They are ideal for uncovering patterns of care. If information from the medical records is
16
17 needed, the results of these analyses can then be supplemented by focused clinical reviews at the
18
19 local level. Also, The RER has a system in place to monitor the quality of diagnosis and
20
21 procedure coding in their hospital discharge abstract data. Controls at both the hospital and
22
23 regional level assess the validity of coding and the consistency of codes assigned such as
24
25 congruity between sex, age and diagnosis and between diagnosis and procedure. The existence
26
27 of the RER administrative database made it feasible to develop the models described in this
28
29 article at relatively low cost and to update the models over time without additional data
30
31 collection that others have found necessary.¹³
32
33
34
35
36
37

38 Currently, these risk scores are being integrated with other information in profiles of high-risk
39
40 patients furnished to providers in 12 newly formed medical homes, including 83 primary care
41
42 physicians serving a total of about 100,000 patients, in the Parma Local Health Authority located
43
44 in RER. Along with the risk scores, this information includes data about previous
45
46 hospitalizations, use of referrals, medications, long-term care and home care services, and a
47
48 number of process-like quality indicators for diabetic and cardiovascular patients, and for
49
50 appropriate medication use in older patients.

59
60

1
2
3 We believe that the Italian health care system offers a number of advantages in the goal of
4 reducing potentially avoidable hospitalization. Every Italian must enroll with a primary care
5 physician. The population is quite stable with modest levels of change of residence or change of
6 primary care physician. Every Italian is entitled to health care with little or no cost at the point
7 of service. There is no problem with loss of, or change in, insurance coverage. Primary care
8 physicians are primarily paid on a per capita basis. But the Emilia-Romagna region has the
9 ability to negotiate incentive payments designed to address and monitor improvements in
10 medical management such as that addressed in our study.
11
12
13
14
15
16
17
18
19
20
21
22

23 Of course, model results need to lead to effective interventions to have a positive impact on
24 patient care. To this end, we are working with the physicians, nurses, and other health care
25 professionals as well as the administration of the newly formed Medical Homes in Parma to
26 assist them in understanding how to use the results of these models and in developing potentially
27 effective interventions. The individual profiles of high risk patients provided to the health care
28 team in the Medical Homes allow them to trigger specific actions such as inviting patients to
29 enroll in disease management programs for chronic problems such as heart failure, chronic
30 obstructive pulmonary disease, or diabetes mellitus, activating home health assistance, initiating
31 a medication review, or recommending that the patient come in for an office visit. An evaluation
32 of the use and usefulness of the profiles and intervention is under way.

Figure 1. Model calibration: Predicted risk and observed prevalence of hospitalization or death in 2012 by predicted risk decile groups.

Contributorship statement: DZL, RG, VM, and JSG were responsible for the conceptualization of this project. MR, JM, and ML were responsible for creation of the datasets used in this project. DZL, VM, MR, and JSG were responsible for the definition of analytical variables. SWK, MR, ML and JM were responsible for modeling and statistical analysis. DZL managed the research team. RG and JSG advised on the analyses and results. All authors contributed to the preparation of the manuscript.

Competing interests: All authors have completed the Unified Competing Interest form and declare grants from the Regione Emilia-Romagna (Louis, Robeson, McAna, Maio, Keith, Liu, Gonnella) during the conduct of the study. Louis and Gonnella declare personal fees from Truven Health Analytics, The National School of Public Health, Portugal, INSIEL Mercato.

Funding: This research was funded by the Agenzia Sanitaria e Sociale of the Emilia-Romagna Region, Italy. The resulting models are being used by the Local Health Authority of Parma, Italy and the Patient Centered Medical Homes located in the Parma Local Health Authority.

Data Sharing: No additional data available.

Abstract

Objectives: Develop predictive models using an administrative health care database that provide information for Patient Centered Medical Homes to proactively identify patients at risk of hospitalization for conditions that may be impacted through improved patient care.

Design: Retrospective health care utilization analysis with multivariate logistic regression models.

Data: A population-based longitudinal database of residents served by the Emilia-Romagna, Italy health service in the years 2004-2012 including demographic information and utilization of health services by 3,726,380 people age ≥ 18 years.

Outcome measures: Models designed to predict risk of hospitalization or death in calendar year 2012 for problems that are potentially avoidable were developed and evaluated using the area under the receiver operating curve C-statistic, in terms of their sensitivity, specificity, and positive predictive value, and for calibration to assess performance across levels of predicted risk.

Results: Among the 3,726,380 adult residents of Emilia-Romagna at the end of 2011, 449,163 (12.1%) were hospitalized in 2012; 4.2% were hospitalized for the selected conditions or died in 2012 (3.6% hospitalized, 1.3% died). The C-statistic for ~~the model~~ predicting 2012 outcomes was 0.856. The model was well calibrated across categories of predicted risk. For those patients in the highest predicted risk decile group, the average predicted risk was 23.9% and the actual prevalence of hospitalization or death was 24.2%.

1
2
3 **Conclusions:** We have developed a population-based model using a longitudinal administrative
4 database that identifies the risk of hospitalization for residents of the Emilia-Romagna region
5
6 with a level of performance as high as, or higher than, similar models. The results of this
7
8 model, along with profiles of patients identified as high risk are being provided to the physicians
9
10 and other health care professionals associated with the Patient Centered Medical Homes to aid in
11
12 planning for care management and interventions that may reduce their patients' likelihood of a
13
14 preventable, high-cost hospitalization.

17
18
19
20
21
22

23 **Strengths and Limitations of this study:**

- 24 • This study included the entire adult population of the Emilia-Romagna Region of Italy,
25 over 3.7 million people.
- 26 • The study used an existing longitudinal administrative health care database with both the
27 advantage of much lower cost than new data collection and the disadvantage of potential
28 errors in administrative data.
- 29 • The results of the study are being used to assist in the development of newly formed
30 Patient Centered Medical Homes.

Introduction

The predominant healthcare delivery system, which has been a passive model, reacting to patients' problems, is shifting to a more proactive model designed to take the initiative in providing care for an increasingly older population that has a greater prevalence of chronic conditions, often with multiple medical and social needs. These changes are driving the reorganization of the primary care system, emphasizing coordination and cooperation among healthcare professionals.^{1,2,3} Among the approaches to addressing this need has been the establishment of ~~primary care organizations incorporating integrated teams of physicians and other healthcare professionals that “seek to increase the influence of primary care professionals, and in particular general practitioners (GPs), in health planning and resource allocation.”~~ ~~Prominent among these new models of primary care is the Patient Centered Medical Homes, an~~ organizations in which ~~a~~ teams of healthcare providers ~~is~~ are engaged in delivering comprehensive, coordinated, patient-centered care to patient defined populations.

Primary care has a central role in the Italian National Health Service (NHS). Twenty one regional governments are responsible for ensuring the delivery of a health benefits package through a network of geographically defined, population-based Local Health Authorities. Primary care physicians work for these authorities as independent contractors and act as “gatekeepers” for specialty and other referral services for their patients.⁴

With the belief that a strong primary care system is conducive to improving population health, the NHS initiated reforms that encouraged primary care physicians to organize into collaborative arrangements. To this end, the Regione Emilia-Romagna (RER), a large northern region with a population of about 4.5 million, has recently launched a plan in its 11 Local Health Authorities to

1
2
3 establish Patient-Centered Medical Homes to better coordinate patient care and help patients
4
5 avoid unnecessary hospitalizations.
6
7

8
9 ~~The identification of those patients who would benefit most from outreach efforts is fundamental~~
10 ~~to achieving these goals of promoting and practicing population health in Patient-Centered~~
11 ~~Medical Homes. To accomplish this, predictive models and risk stratification tools are needed to~~
12 ~~identify patients at risk of a worsening of their health status. According to Knutson and Bella,⁵~~
13 ~~“Predictive models are data-driven, decision-support tools that estimate an individual’s future~~
14 ~~potential health care costs and/or opportunities for care management.” A good model will~~
15 ~~identify as many of these patients as possible while excluding those for whom these interventions~~
16 ~~would be unnecessary or ineffective.~~
17
18
19
20
21
22
23
24
25
26
27

28 The identification of those patients who would benefit most from outreach efforts is fundamental
29 to achieving these goals of promoting and practicing population health in Patient-Centered
30 Medical Homes. The RER has established three objectives for this project: 1) develop predictive
31
32 models to identify patients at high risk of hospitalization or death, 2) create “risk of
33
34 hospitalization” patient profiles that provide information about their high-risk patients to the
35
36 general practitioners in the newly formed Patient-Centered Medical Homes, and 3) assess the
37
38 extent to which these models and reports provide additional information useful in the
39
40 identification of patients who may benefit from case management or disease management.
41
42
43
44
45
46
47

48
49 This paper will address the first of the three goals. We describe the development of a predictive
50
51 model using the RER’s regional longitudinal administrative health care database to help identify
52
53 patients who are most at risk of hospitalization for conditions that may be impacted through
54
55 improved patient care. This model will then be used to inform the providers associated with the
56
57

1
2
3 Patient-Centered Medical Homes and aid in their planning for care management and
4
5 interventions that can reduce their patients' likelihood of a preventable, high-cost hospitalization.
6
7
8
9

10 11 **Methods**

12 13 Study Data and Study Population

14
15
16 The model was developed using the population-based longitudinal health care database of the
17 residents served by the RER Health Service in the years 2004 through 2012.⁶ This
18 administrative database includes demographic information for all residents (gender, birth and
19 death dates, location of current residence, and primary care physician), hospital discharge
20 abstract data (ICD-9-CM diagnosis and procedure codes, and admission and discharge dates),
21 emergency room utilization information, outpatient pharmacy data at the individual prescription
22 level, specialty care (laboratory, diagnostics, therapeutic procedures, rehabilitation, and specialist
23 visits), home health data, and information on each primary care physician in the region. Each
24 patient has an anonymous identifier assigned by the RER so that an individual's utilization can
25 be tracked over time without jeopardizing patient privacy.
26
27
28
29
30
31
32
33
34
35
36
37
38
39

40
41 The study population consisted of all residents of the RER who were at least 18 years of age and
42 still alive as of 31st December 2011. [Health care utilization data from 2011 and history variables
43 using data from 2004 through 2010 were used to predict outcomes in 2012.](#)
44
45
46
47
48
49
50

51 Dependent Variable

52
53
54 The dependent variable was defined as the occurrence of a hospitalization for problems that are
55
56
57
58
59
60

1
2
3 potentially avoidable, or whose progression may have been avoided or delayed through
4
5 appropriate patient care, or the death of the individual, either in or out of the hospital, for any
6
7
8 reason in 2012. [We included deaths in the dependent variable since we believe that, for](#)
9
10 [example, a patient with coronary artery disease who dies secondary to an acute myocardial](#)
11 [infarction, should be included in the dependent variable even if the death is out of the hospital.](#)
12
13

14
15 We decided to not limit the hospitalization to emergency admissions, since a planned admission
16
17 may also be an indicator of a worsening medical problem. In order to operationally define the
18
19 dependent variable, we (authors JSG and DZL) reviewed the Disease Staging^{7,8} primary
20
21 diagnostic category and severity stage of all day and inpatient hospital admissions (for adults age
22
23 18+) in RER for one year, to select those admissions that should be included in the dependent
24
25 variable.
26
27

28
29
30 [Deliveries](#) [Admissions to deliver a baby](#), admission for dental diseases or admissions for vague
31
32 signs or symptoms with no identified etiology were excluded. Admissions for problems that are
33
34 not predictable/preventable were excluded while those where screening may identify problems
35
36 that can potentially be treated to avoid progression were included. For example, admissions for
37
38 stage 1, chronic cholecystitis or cholelithiasis were excluded, but admissions for advanced stage
39
40 2 or 3 complications such as ascending cholangitis or pancreatitis were included.
41
42
43
44

45 We felt that inclusion of hospitalization for cancer in the dependent variable should depend on
46
47 the ability to either prevent or avoid progression of the disease. We therefore included colon
48
49 cancer and cervical cancer in the definition because they are potentially preventable but excluded
50
51 all other cancers where prevention/prediction is not currently possible.
52
53
54

55 Inclusion of injuries, burns, or toxic reaction to prescription or non-prescription drugs would
56
57

1
2
3 ideally be based on the cause of these problems. Since the etiology of these problems is typically
4
5 not available in the administrative data being used in this project, we made the decision to
6
7 include or exclude based on our subjective judgment of the likelihood of preventability. For
8
9 example, adverse drug reactions were included but burns were excluded from the definition of
10
11 the dependent variable.
12
13

14
15
16 There is no obvious medical reason for a hospital admission for patients with stage 1 diabetes
17
18 mellitus or stage 1 essential hypertension without complications. These problems are typically
19
20 treatable in the outpatient setting. A hospitalization implies a potential problem in the care of
21
22 these patients, so we decided to include these admissions as a part of the dependent variable.⁹
23
24
25
26
27
28
29
30

31 Independent Variables

32
33 A broad range of candidate predictor variables was developed taking advantage of the RER
34
35 administrative data. The independent variables used for modeling were defined from the RER
36
37 administrative data for the years 2004 through 2011. Demographic data included patient age,
38
39 sex, and geographic location of residence. We developed a mapping to broad disease categories
40
41 defined primarily in terms of the affected body system from home health care data, pharmacy
42
43 data, and hospital discharge abstract data. (See Appendix 1.)
44
45
46
47
48
49

50 For those patients who had been hospitalized, more specific diagnostic data were available. We
51
52 reviewed the classification of patients hospitalized historically using the Disease Staging
53
54 diagnostic category and disease severity stages.^{7,8} Based on the frequencies specific diagnostic
55
56

1
2
3 category/stage predictor variables were defined for either specific stages of frequent diseases, or
4
5 by combinations across similar categories. Predictor variables were defined based on the number
6
7 of emergency room visits using the RER classifications system for the urgency of the visit.
8
9

10
11
12 Pharmacy data were used to identify polypharmacy¹⁰ (defined as the simultaneous use of five or
13
14 more active ingredients for at least 15 consecutive days), potential drug-drug interactions
15
16 (DDI)¹¹ and potentially inappropriate medication use in patients¹² 65 years and older. Since
17
18 cardiovascular disease is highly prevalent, we reviewed the use of cardiovascular drugs and
19
20 created a variable for each of the following 11 classes of drugs (oral anti-coagulants, beta-
21
22 blockers, angiotensin converting enzyme / angiotensin II receptor blockers, anti-platelets,
23
24 calcium channel blockers, anti-arrhythmics, digitalis glycosides, nitrates, diuretics, [alpha-](#)
25
26 blockers, statins) to account for the complexity of therapeutic regimen at the patient level.
27
28
29
30
31
32
33

34 To take advantage of the fact that the RER database includes multiple years of data, we created
35
36 history variables using the utilization for each year of data available. Since we were working
37
38 with the 2011 data to predict hospitalization or death in 2012, we created history variables based
39
40 on 2004-2010 data. This set included 83 of the diagnostic category/stage variables as well as 11
41
42 variables based on pharmacy utilization such as exposure to polypharmacy and use of
43
44 cardiovascular drugs. If the individual had a history of a disease in any of the years from 2004 to
45
46 2010 they were flagged as having a history of that disease and this was used as a potential
47
48 predictor variable.
49
50
51
52
53
54

55 Modeling

1
2
3 Logistic regression models were used to estimate predicted probabilities for the occurrence of an
4
5 inpatient hospital stay for the selected conditions or death for individual patients. Risk of
6
7 hospitalization or death, and the variables that relate to those risks are highly dependent on age
8
9 and gender. Regression models were fit in each of 14 gender and age strata using SAS Version
10
11 9.2 (SAS Institute, Cary NC). A stepwise process with relaxed covariate entry and retention
12
13 criteria (inclusion p-value ≤ 0.8 , retention ≤ 0.5) was used. At each step in this process, an
14
15 attempt is made to remove any unimportant variables from the model before adding a potentially
16
17 important variable. Each addition or deletion of a variable to or from a potential model is a
18
19 separate step and, at each step, a new model is fitted. This process results in a reduced, but robust
20
21 set of independent variables that predict outcome or that might have importance as adjustment
22
23 terms for the model in each age/gender stratum.
24
25
26
27
28
29
30
31
32
33

34 Evaluation of the Models

35
36 The predictive accuracy of the modelling was evaluated using C-statistics (the area under the
37
38 receiver operating characteristics curve), along with three measures traditionally used with
39
40 clinical screening tools: sensitivity, specificity and positive predictive value.
41
42
43

44 C-statistics were used to evaluate the models in two ways. The first evaluation consisted of
45
46 fitting the model developed using utilization and demographic data from 2011, along with
47
48 historical variables based on 2004-2010 data, and outcomes (hospitalization or death) from 2012
49
50 and then computing a C-statistic to evaluate how the models performed at predicting those
51
52 outcomes on which the models were conditioned. However, this evaluation is not consistent with
53
54 evaluating how the data are used in practice. In practice, we have current predictor information,
55
56
57
58
59
60

1
2
3 but the outcomes have not been realized. To better estimate how the models are likely to perform
4
5 in this setting, we fit models to outcomes data up to a year prior to the most current available
6
7 (e.g., 2011 outcomes modelled with predictors from 2010, along with historical variables based
8
9 on 2004-2009 data). We then computed a C-statistic for projections made on the risk of
10
11 hospitalization or death outcomes (in 2012) using the next year's predictor information (in 2011).
12
13 This way, the models are forced to make projections into the future, but we have the actual
14
15 observed outcomes data to evaluate the modelling process as it would be used in practice. The
16
17 resulting C-statistics obtained from these two model runs were compared.
18
19
20
21
22

23 In order to evaluate the performance of the model across different risk thresholds we classified
24
25 predicted risk scores. "Very high risk" was defined as patients with a predicted risk of
26
27 hospitalization or death in the following year of $\geq 25\%$ while "high risk" was defined as patients
28
29 with a predicted risk of hospitalization of 15-24%. These risk thresholds were selected after
30
31 consultation with physicians practicing in the medical homes to yield a total of about 10% of the
32
33 1,500 patients enrolled with a typical primary care physician.
34
35
36
37

38 **Results**

39
40
41 Among the 3,726,380 adult residents of Emilia Romagna at the end of 2011, 449,163 (12.1%)
42
43 were hospitalized in 2012; 4.2% were hospitalized for the selected conditions defined earlier or
44
45 died in 2012 (3.6% hospitalized, 1.3% died).
46
47
48

49 Table 1 shows the distribution of the demographics (age and gender), number of chronic
50
51 conditions, body systems impacted by the selected chronic conditions, polypharmacy and
52
53 inappropriate prescribing among the eligible RER residents, as of December 31, 2011. ~~The~~
54

57

table 1 also compares these characteristics of the total adult population of the region to the subgroups of the population classified in the “very high risk” and “high risk” categories. Based on the model results, 114,255 individuals were identified as having a predicted risk of hospitalization or death in 2012 of $\geq 25\%$ and classified as “very high risk.” An additional 134,610 individuals had a predicted risk of hospitalization or death in 2012 of 15-24% and were classified as “high risk.”

Table 1. Demographic and clinical characteristics of the Regione Emilia-Romagna population, overall and by risk category

	Total Population*		Very High Risk**		High Risk**

Any potentially inappropriate medications (age 65 years or older)^{^^}	257,033	25.5%	51,055	48.7%	49,003	39.2%

* Adults (age 18 or older) and alive at 31 December 2011.

** "Very high risk" was defined as patients with a predicted risk of hospitalization or death in the following year of $\geq 25\%$ while "high risk" was defined as patients with a predicted risk of hospitalization of 15-24%.

Men only.

Women only.

[^] Polypharmacy is defined as the simultaneous use of five or more active ingredients for at least 15 consecutive days.

^{^^} The list of potentially inappropriate medications can be found in: Maio V, Del Canale S, Abouzaid S. Using Explicit Criteria to Evaluate the Quality of Prescribing in Elderly Italian Outpatients: A Cohort Study. *Journal of Clinical Pharmacy and Therapeutics* 2010;35:219-229.

There was little difference across the risk categories by gender. Age distributions for the "very high risk" and "high risk" groups were shifted more towards the older age groups than those in the overall study population. Residents age 85 or older represented about 4.5% of the RER population, but about 50% of the "very high" and "high" predicted risk groups. More than 75% of the residents over age 85 were classified as "very high" or "high" risk. However, age alone was not sufficient to ~~their~~ predict their risk. For example, residents between 75 and 84 years of

1
2
3 age made up 23% of the “very high” risk group and 41% of the “high” risk group, but over 85%
4
5 of the residents in this age category had neither “very high” nor “high” predicted risk.
6
7

8
9 Across age and gender strata, demographics and health care utilization experience in 2011 were
10
11 the most commonly used independent variables for predicting hospitalization or death in 2012.
12
13 Selected history variables flagging chronic problems such as cardiovascular disease, diabetes
14
15 mellitus and chronic renal failure and a history of prescriptions for cardiovascular medications
16
17 and polypharmacy were also significant predictors.
18
19

20
21 The residents in the two higher risk groups were more likely than others to have multiple chronic
22
23 diseases and to experience polypharmacy and inappropriate medication use. The residents
24
25 identified as “very high risk” or “high risk” by the model also showed a number of striking
26
27 differences from others in terms of the occurrence of some of the most prevalent health
28
29 conditions by type and body system. Although cardiovascular conditions were not uncommon in
30
31 the total adult population (26.0%), they were far more common among those classified as “very
32
33 high risk” and “high risk” (84.2% and 77.1%, respectively). Similarly, gastrointestinal conditions
34
35 affected 15.6% of the total population, but were diagnosed in 65.4% of the “very high risk” and
36
37 49.3% of the “high risk” patients. Cancer occurred in 2.7% of the total population, but 20.9% of
38
39 the “very high risk” and 10.6% of the “high risk” patients had a cancer diagnosis. Mental health
40
41 problems were identified in 7.8% of the adult population, but in 34.2% of the “very high risk”
42
43 and 25.0% of the “high risk” patients.
44
45
46
47
48
49

50
51 The C-statistic for the model of 2012 outcomes developed using 2011 predictors and the
52
53 C-statistic based on the parameters from the model of 2011 outcomes regressed on 2010
54
55 predictors applied to the 2011 predictors and 2012 outcomes were very similar (0.856 and 0.853,
56
57

respectively). These results suggest that the relationship between predictors and risk of hospitalization changed little in one year and that model parameters developed in a prior year can be used reliably with the most current year's data to predict unknown outcomes in the next year with only a minimal loss in performance in this population.

Table 2 shows the sensitivity, specificity, positive predictive value and number of true positives for the model at the two selected cut-off points. The sensitivity (percentage of patients actually hospitalized who had been identified by the model as having a predicted risk higher than the cut-off point) was 29.8% for those with the "very high" risk scores. This percentage represents 46,950 of the 157,550 residents of the region who were hospitalized for a selected condition or died in 2012. If we modify the risk score threshold to include individuals with a predicted risk of hospitalization for selected conditions or death of $\geq 15\%$ (i.e., both the "very high risk" and the "high risk" patients) the sensitivity is .471. The true negative rate (specificity) is very high for both risk thresholds (.981 and .951, respectively).

Measure	Cut-off points for comparison	
	"Very high risk"*	"Very high risk"* + "High risk"**
Sensitivity [#]	0.298	0.471
Specificity ^{##}	0.981	0.951
Positive Predictive Value [^]	0.411	0.298
True positives ^{^^}	46,950	74,196
* "Very high risk" is defined as patients with a predicted risk of hospitalization of $\geq 25\%$. ** "Very high risk" + "High risk", is defined as patients with a predicted risk of hospitalization of $\geq 15\%$. # Sensitivity is defined as the proportion of those hospitalized who were predicted to be hospitalized (true positive rate).

The model appears to be well calibrated across levels of risk. ~~The~~ Figure 1 depicts the RER population divided into groups by deciles of predicted risk of hospitalization or death from the models. The observed prevalence of hospitalization or death is compared to the average predicted risk among individuals in each of the ten predicted risk groups. For example, the overall rate of hospitalization for the selected conditions or death in 2012 was 4.2%. For those patients in the highest predicted risk decile group, the average predicted risk was 23.9% and the actual prevalence of hospitalization or death was 24.2%. (Regression coefficients and significance levels of independent variables for models for each of 14 age and gender strata are displayed in Appendix 2.)

49
50
51
52
53
54
55
56
57
58
59
60

We have developed a population-based model that identifies the risk of hospitalization for all adult RER residents and does so with a level of performance ($c=0.85$) as high as, or higher than, similar models. In addition, we believe that the definition of the dependent variable chosen for our models increases the probability that they are identifying patients who risk can potentially be improved by appropriate care. A systematic review by Kansagara¹³ of models designed to predict readmissions, showed C-statistic results in the range of 0.55 to 0.83. Recent work by

1
2
3 Billings et al¹⁴ to develop models predictive of emergent admissions in the UK had results
4 ranging from 0.73 to 0.78. Li Wang, et al. (2013),¹⁵ using information available through the
5
6 [United States Department of Veterans Affairs US Veteran's Administration](#) that also included
7 lab data, demonstrated Ce-statistics of 0.81 and 0.79, respectively, for their models of 90-day or
8
9 12-month hospitalization or death outcomes. At a predicted risk of $\geq 25\%$ our model had a
10
11 Positive Predictive Value (PPV) of .411. Billings et al¹⁴ reported a PPV of .417 at a risk
12
13 threshold of 30. There is a trade-off in using our model, or any predictive model, between the
14
15 threshold for follow-up and predictive accuracy. A lower risk threshold would identify more
16
17 patients but with a lower prevalence of hospitalization or death.
18
19

20
21 Although previous studies have developed models predictive of hospital care, these models fall
22
23 short of the needs of the Patient Centered Medical Homes being implemented in RER. Typically,
24
25 these models have focused on specific age groups,¹⁶ conditions, or types of admissions, such as
26
27 emergent¹⁴ or unplanned admissions or rehospitalizations, or health insurance plans in the United
28
29 States, including private insurance plans, Medicare and Medicaid plans.^{17,18} The models we have
30
31 developed are applied to the entire adult population of RER. They use existing administrative
32
33 data, which makes them cost effective to apply.
34
35
36
37
38
39
40
41
42

43 Patient Centered Medical Homes, including those instituted in RER, are responsible for
44
45 addressing the needs of their population and making the best use of their finite resources to
46
47 accomplish this. Preventing unnecessary admissions could improve both the quality of care and
48
49 health status of the enrolled population, and result in a substantial savings. To accomplish this,
50
51 predictive models and risk stratification tools such as those developed for this project are needed
52
53
54
55
56
57
58
59
60

1
2
3 to identify patients at risk of preventable admissions and provide information that can be used by
4
5 the medical homes to help manage care.
6
7

8
9 There are some limitations to the model. The model is developed from administrative data.

10
11 Administrative data are collected for reimbursement and tracking utilization and not for medical

12
13 research. They lack the clinical specificity that would [be](#) desirable in assessing an individual's

14
15 medical problems. [Patients with medical problems who have not used the services included in](#)

16
17 [the database cannot be identified.](#) While the hospital discharge abstract data do include

18
19 diagnostic information coded using ICD-9-CM, no similar data are available for outpatient

20
21 encounters in the RER database. The mortality data available for this project did not include

22
23 information about cause of death. Therefore, some proportion of patients whose death was not

24
25 predictable were included, limiting model performance. In addition, our models use prior

26
27 utilization among the predictor variables. With the administrative data we cannot distinguish

28
29 between appropriate and inappropriate treatment which may bias our results.
30
31
32
33
34
35

36 Despite the limitations of administrative data, they have many advantages for this project: they

37
38 are readily available, relatively inexpensive to analyze and cover large populations over many

39
40 years. They are ideal for uncovering patterns of care. If information from the medical records is

41
42 needed, the results of these analyses can then be supplemented by focused clinical reviews at the

43
44 local level. Also, The RER has a system in place to monitor the quality of diagnosis and

45
46 procedure coding in their hospital discharge abstract data. Controls at both the hospital and

47
48 regional level assess the validity of coding and the consistency of codes assigned such as

49
50 congruity between sex, age and diagnosis and between diagnosis and procedure. The existence

51
52 of the RER administrative database made it feasible to develop the models described in this
53
54
55
56
57
58
59
60

1
2
3 article at relatively low cost and to update the models over time without additional data
4
5 collection that others have found necessary.¹⁴
6
7

8
9 Currently, these risk scores are being integrated with other information in profiles of high-risk
10
11 patients furnished to providers in 12 newly formed medical homes, including 83 primary care
12
13 physicians serving a total of about 100,000 patients, in the Parma Local Health Authority located
14
15 in RER. Along with the risk scores, this information includes data about previous
16
17 hospitalizations, use of referrals, medications, long-term care and home care services, and a
18
19 number of process-like quality indicators for diabetic and cardiovascular patients, and for
20
21 appropriate medication use in older patients.
22
23

24
25
26 We believe that the Italian health care system offers a number of advantages in the goal of
27
28 reducing potentially avoidable hospitalization. Every Italian must enroll with a primary care
29
30 physician. The population is quite stable with modest levels of change of residence or change of
31
32 primary care physician. Every Italian is entitled to health care with little or no cost at the point
33
34 of service. There is no problem with loss of, or change in, insurance coverage. Primary care
35
36 physicians are primarily paid on a per capita basis. But the Emilia-Romagna region has the
37
38 ability to negotiate incentive payments designed to address and monitor improvements in
39
40 medical management such as that addressed in our study.
41
42
43
44

45
46 Of course, model results need to lead to ~~an~~ effective interventions to have a positive impact on
47
48 patient care. To this end, we are working with the physicians, nurses, ~~and~~ and other health care
49
50 professionals as well as the administration of the newly formed Medical Homes in Parma to
51
52 assist them in understanding how to use the results of these models and in developing potentially
53
54 effective interventions. The individual profiles of high risk patients provided to the health care
55
56
57
58
59
60

1
2
3 team in the Medical Homes allow them to trigger specific actions such as inviting patients to
4 enroll in disease management programs for chronic problems such as heart failure, chronic
5 obstructive pulmonary disease, or diabetes mellitus, activating home health assistance, initiating
6 a medication review, or recommending that the patient come in for an office visit. An evaluation
7 of the use and usefulness of the profiles and intervention is under way.
8
9
10
11
12
13

14
15
16 In summary, these models provide a means of identifying patients at high risk for hospitalization.
17 The risk predictions, in conjunction with the risk profile, show promise as a useful organizational
18 tool for the regional Patient Centered Medical Homes to develop and implement proactive case
19 management and disease management programs. The RER is reviewing the results of the Parma
20 Local Health Authority pilot project of the profiles. Once their usefulness has been further
21 evaluated, their use will be expanded to other Medical Homes in development in the other Local
22 Health Authorities in the Emilia-Romagna region. If similar data are available, these models can
23 be applied in other Italian regions and other countries investing in organization similar to the
24 Patient Centered Medical Home.

Figure 1 Legend:

Figure 1. Model calibration: Predicted risk and observed prevalence of hospitalization or death in 2012 by predicted risk decile groups.

Contributorship statement: DZL, RG, VM, and JSG were responsible for the conceptualization of this project. MR, JM, and ML were responsible for creation of the datasets used in this project. DZL, VM, MR, and JSG were responsible for the definition of analytical variables. SWK, MR, ML and JM were responsible for modeling and statistical analysis. DZL managed the research team. RG and JSG advised on the analyses and results. All authors contributed to the preparation of the manuscript.

Competing interests: All authors have completed the Unified Competing Interest form and declare grants from the Regione Emilia-Romagna (Louis, Robeson, McAna, Maio, Keith, Liu, Gonnella) during the conduct of the study. Louis and Gonnella declare personal fees from Truven Health Analytics, The National School of Public Health, Portugal, INSIEL Mercato.

Funding: This research was funded by the Agenzia Sanitaria e Sociale of the Emilia-Romagna Region, Italy. The resulting models are being used by the Local Health Authority of Parma, Italy and the Patient Centered Medical Homes located in the Parma Local Health Authority.

Data Sharing: No additional data available.

Appendix 1: Mapping to Body System or Etiology Groups

Body System or Etiology Group	Hospital Discharge data	Outpatient pharmacy data	Home health care	Specialty visits
Cancer	Neoplasm, Malignant: Cardiovascular, Hypopharynx, Oral Cavity, Oropharynx, Salivary Glands and Mandible, Other Endocrine System, Larynx, Glottis, Larynx, Subglottic, Larynx, Supraglottic, Nasopharyngeal, Sinuses, Ocular Melanoma, Other Eye and Periocular, Colon and Rectum, Esophagus, Small Bowel, Stomach, Other Gastrointestinal System, Bladder, Urinary, Kidneys, Other Genitourinary System, Breast (Female), Cervix Uteri, Endometrium, Ovaries, Vagina, Vulva, Other Female Genitalia, Hodgkin's Lymphoma, Multiple Myeloma, Mastocytosis, Pancreas, Other Hepatobiliary Tract, Breast (Male), Penile, Prostate, Testicular, Primary Bone, Waldenstrom's Macroglobulinemia, Nonspecific Sites, Unspecified Primary Site, Lungs, Bronchi, or Mediastinum, Hodgkin's Disease Lymphocytic Depletion, Hodgkin's Disease Lymphocytic Predominance, Hodgkin's Disease Mixed Cellularity, Hodgkin's Disease Nodular Sclerosis, Lymphatic and Hematopoietic (Other Types), Lymphoma, Cutaneous T Cell (Mycosis Fungoides), Lymphoma (Diffuse Mixed Small and Large Cell), Lymphoma (Diffuse Large Cell), Lymphoma (Follicular Predominantly Large Cell), Lymphoma (Histiocytic Cell), Lymphoma (Lymphoblastic), Other Respiratory System, Carcinoma (Basal Cell stage 2/3), Carcinoma (Squamous Cell), Melanoma, Other Skin and Soft	Antineoplastics 5HT3 Antagonists	2005-2009: Visits prescribed due to the presence of cancer. Beginning in 2010, the following ICD-9-CM codes were in the record: 140-208, 235-239, V10, V16	Visits prescribed for radiation therapy, or for Injection or infusion of chemotherapeutic Substances for cancer treatment

A-1

Body System or Etiology Group	Hospital Discharge data	Outpatient pharmacy data	Home health care	Specialty visits
	Tissue Neoplasm: Pheochromocytoma, Eyelid, Central Nervous System, Lymphatic or Hematopoietic Leukemia: Acute Lymphocytic, Acute Nonlymphocytic, Chronic Lymphocytic, Chronic Myelogenous, Other Types Encounter for: Chemotherapy, Radiation Therapy ICD-9-CM Procedure codes: 99.25, 99.28, 00.10,00.15,92.2x			
Cardiovascular	Aneurysm: Abdominal, Thoracic Anomaly: Patent Ductus Arteriosus, Atrial Septal Defect, Atrioventricular Defects, Coarctation of the Aorta, Other Congenital Heart Disease, Pulmonary Valve Stenosis, Tetralogy of Fallot (stage 3), Transposition of the Great Arteries, Ventricular Septal Defects, Other Circulatory System Aortic: Regurgitation, Stenosis Mitral: Regurgitation, Stenosis Neoplasm: Benign of the Cardiovascular System Arrhythmias, Cardiomyopathies, Conduction Disorders, Congestive Heart Failure, Coronary Artery Disease Prior Coronary Revascularization, Coronary Artery Disease w/o Prior, Coronary Revascularization, Essential Hypertension, Infective, Endocarditis, Pericarditis: Chronic (stage 2/3), Viral or Traumatic (stage 2/3) Periarteritis Nodosa, Raynaud's Disease, Thromboangiitis,	Oral anti-coagulants beta-blockers ACE/ARB anti-platelets calcium channel blockers anti-arrhythmics digitalis glycosides nitrates diuretics alfa-blockers statins	2005-2009: Visits prescribed due to the presence of Congestive Heart Failure or not-well defined cardiopathy, and other diseases of cardiovascular system. Beginning in 2010, the following ICD- 9-CM-CM codes were in the record: 390-454,456-459

Body System or Etiology Group	Hospital Discharge data	Outpatient pharmacy data	Home health care	Specialty visits
	Obliterans, Thrombophlebitis, Tibial, Iliac, Femoral, or Popliteal Artery Disease, Varicose Veins of Lower Extremities, Secondary Hypertension, Budd Chiari Syndrome, Rheumatic Fever (stage 2/3) Vasculitis Other: Atherosclerosis, Cardiac Conditions, Cardiovascular Symptoms, Circulatory Disorders, Diseases of Arteries, Diseases of Veins, Disorders of Pulmonary Circulation, Lymphatic Disorders			
Endocrine	Adrenal Insufficiency, Cushing's Syndrome, Diabetes insipidus, Diabetes Mellitus Type 1, Diabetes Mellitus Type 2 and Hyperglycemic States,Hyperthyroidism, Hypoglycemia, Hypothyroidism, Monotropic Hormone Deficiency, Primary Amyloidosis, Thyroiditis, Klinefelter's Syndrome, Turner's or Noonan's Syndrome, Obesity Goiter: Nontoxic or Euthyroid (stage 2/3) Neoplasm, Benign: Acromegaly, Adenoma, Parathyroid, Hyperparathyroidism, Primary Hyperaldosteronism, Other Endocrine System Neoplasm, Malignant:Thyroid Other: Endocrine Disorders, Electrolyte Disorders, Nutritional and Metabolic Disorders Anomaly: Adrenal Hyperplasia	Insulins biguanides sulfonylureas vasopressin thyroid replacement antithyroid agents	2005-2009: Visits prescribed due to the presence of diabetes mellitus Beginning in 2010, the following ICD-9-CM codes were in the record: 240-278	

Body System or Etiology Group	Hospital Discharge data	Outpatient pharmacy data	Home health care	Specialty visits
Ear, Nose, Throat	Diseases of Salivary Gland, Incl. Parotitis or Benign Tumors, Other Disorders of Oral Cavity (stage 2), Cholesteatoma, Meniere's Disease, Otitis Media, Sinusitis Hearing Loss due to: Acoustic Trauma, Otosclerosis Neoplasm, Benign: Larynx, Sinuses, Oral Cavity and Pharyngeal Structures Pharyngitis: Non-Streptococcal (stage 2)			
Eye	Cataract, Conjunctivitis: Bacterial, Contusion or Ruptured Globe, Dacryostenosis or Dacryocystitis, Detachment of the Retina, Ectropion or Entropion (Abnormal Lower Lid Position), Endophthalmitis, Foreign Body: Orbit, Fracture: Orbit, Blow-Out, Fungal Infection of the Eye, Glaucoma, Hypovitaminosis A, Laceration: Cornea, Macular Degeneration, Orbital Infection, Prematurity: Retinopathy, Ptosis of Upper Lid, Retrobulbar Orbital Hemorrhage, Trachoma, Other Eye Disorders Injury or Laceration: Eyelid, Periocular, Cornea, Conjunctiv Injury: Eyes, Nonionizing Radiation Keratitis: Acanthamoeba, Bacterial Neoplasm, Benign: Eye	Sympaticomimetic agents parasympaticomimetic agents anhydrase inhibitors ophthalmic beta blockers		
Gastrointestinal	Anorectal Suppuration, Celiac Disease, Clostridium difficile Colitis, Crohn's Disease, Diverticular Disease, Food Poisoning: Other Organisms (stage 3), Functional Digestive Disorders, Gastritis, Hemorrhoids, Hernia (External), Hernia (Hiatal or Reflux Esophagitis), Intussusception (stage 2), Irritable Bowel Syndrome, Gastroenteritis	Intestinal corticosteroids agents H2 antagonists prostaglandins proton pump inhibitors	2005-2009: Visits prescribed due to the presence of Gastrointestinal Diseases Beginning in 2010,

Body System or Etiology Group	Hospital Discharge data	Outpatient pharmacy data	Home health care	Specialty visits
	Neoplasm, Benign: Adenomatous Polyps, Colon, Small Bowel, Other Gastrointestinal System Peptic Ulcer Disease, Salmonellosis (stage 3), Ulcerative Colitis, Vascular Insufficiency of the Bowels, Complications of Gastrointestinal Treatment, Gastroenteritis (stage 2/3) Other Diseases of Esophagus, Stomach, and Duodenum Other Gastrointestinal Disorders, Other Gastrointestinal Infections (stage 2), Other Gastrointestinal or Abdominal Symptoms Anomaly: Congenital Megacolon, Other Digestive or Hepatobiliary System Burns, Chemical: Esophagus, Stomach, or Small Intestine, Laceration: Esophagus		the following ICD-9-CM codes were in the record: 520-539,550-579	
Genitourinary	Bladder Disorders, Calculus of the Urinary Tract, Glomerulonephritis, Acute, Injury: Urinary Tract, Nephrotic Syndrome (stage 2/3), Renal Failure (stage 2/3), Urethritis, Urinary Tract Infections, Neoplasm, Benign: Urinary Tract, Other Disorders of Kidney or Ureter, Other Urinary Symptoms, Encounter for Dialysis, Anomaly: Defects of Kidney, Defects of Lower Genitourinary Tract, Syphilis: Congenital	Agents for hyperkalemia and hyperphosphatemia	2005-2009: Visits prescribed due to the presence of renal failure and Other diseases of the genito-urinary system Beginning in 2010, the following ICD-9-CM codes were in the record: 580-629	Visits prescribed for dialysis

Body System or Etiology Group	Hospital Discharge data	Outpatient pharmacy data	Home health care	Specialty visits
Gynecological and Obstetrics	Anomaly: External Female Genitalia, Anomaly: Uterus, Dysfunctional Uterine Bleeding, Endometriosis, Neoplasm, Benign: Ovary (stage 2), Pelvic Inflammatory Disease, Uterine Infection, Uterovaginal Prolapse, Vulvovaginitis, Other Disorders of Female Genital System			
Hematological	Agranulocytosis, Anemia: Aplastic, Acquired (stage 2/3), Folic Acid Deficiency, Hemolytic (stage 2/3), Iron Deficiency, Sickle Cell, Thalassemia, Vitamin B-12 Deficiency, Other Graft versus Host reaction, Hemophilia A or B, Polycythemia Vera, Other Disorders of Blood and Blood-Forming Organs	Iron vitamin B12 folic acids	Beginning in 2010, the following ICD-9-CM codes were in the record: 280-289	
Hepatobiliary	Cholecystitis and Cholelithiasis, Cirrhosis of the Liver (stage 2/3), Disorders of Bilirubin Excretion, Hepatitis A, Hepatitis B, Hepatitis C, Hepatitis D, Hepatitis E, Hepatitis G, Hepatitis (Chemical), Pancreatitis, Wilson's Disease, Neoplasm, Benign: Hepatobiliary System, Other Hepatobiliary and Pancreatic Disorders, Other Hepatobiliary Infections, Other Pancreatic Disorders	Interferons blood substitutes and plasmatic protein fractions		
Immunologic Diseases	Human Immunodeficiency Virus Type I (HIV) Infection, Other Immunodeficient Disorders, Pneumonia: Pneumocystis carinii	Nucleosides and nucleotides reverse transcriptase inhibitors	2005-2009: Visits prescribed due to HIV Infections Beginning in 2010, the following ICD-9-CM codes were in the record: 279

Infectious Diseases	Aspergillosis, Chlamydial Infection Except Trachoma or Pneumonia, Cryptococcosis, Cytomegalovirus Disease (Acquired), Infectious Mononucleosis (stage 2), Mucormycosis, Reye's Syndrome (stage 3), Rubella: Acquired (stage 3), Schistosomiasis, Other Bacterial Infections, Other Fungal Infections, Other Infectious and Parasitic Infections, Other Viral Infections, Cytomegalovirus Disease (Congenital), Parainfluenza Virus Infection, Pneumonia: Chlamydial, Sarcoidosis, Other Respiratory Infections, Scabies		Beginning in 2010, the following ICD-9-CM codes were in the record: 001-139	
Male Genital	Benign Prostatic Hypertrophy, Gonorrhea: Male, Prostatitis	Alfa-adrenoreceptor antagonists testosterone 5-alfa reductase inhibitors		
Musculoskeletal	Vitamin D Deficiency, Dislocation: Knee, Eosinophilia Myalgia Syndrome, Fracture: Acetabulum, Fracture: Calcaneus (stage 2), Fracture: Femur, Except Head or Neck, Fracture: Femur, Head or Neck, Fracture: Fibula (stage 2), Fracture: Humerus (Shaft), Fracture: Humerus (Supracondylar) (stage 2), Fracture: Radial Shaft, Ulna or Olecranon (stage 2), Fracture: Radius, Lower End (stage 2), Fracture: Tibia (stage 2/3), Fracture or Dislocation: Patella (stage 2), Fracture or Sprain: Ankle (stage 2), Fracture, Dislocation, or Sprain: Facial Bones (stage 2/3), Fracture, Dislocation, or Sprain: Foot (stage 2), Fracture, Dislocation, or Sprain: Hip or Pelvis (stage 2/3), Fracture, Dislocation, or	Colchicine uric acid inhibitors antiinflammatory non-steroids gold salts aminoquinolines bisphosphonates calcitonin	2005-2009: Visits prescribed due to the presence of Arthrosis, Arthritis and other osteo-muscular and connective diseases, and Fractures of femurs and other consequences of fractures.	

Body System or Etiology Group	Hospital Discharge data	Outpatient pharmacy data	Home health care	Specialty visits
	Sprain: Humerus (Head) or Shoulder (stage 2), Fracture, Dislocation, or Sprain: Wrist or Hand or Fingers (stage 2), Gout, Herniated Intervertebral Disc, Infectious Arthritis (stage 2/3), Injury, Chest Wall, Injury, Knee, Semilunar Cartilages (stage 2), Injury, Open Wound, or Blunt Trauma: Lower Extremity (stage 2), Injury, Open Wound, or Blunt Trauma: Upper Extremity (stage 2/3), Muscular Dystrophy, Osteoarthritis, Osteochondrodysplasia, Osteomalacia, Osteomyelitis (stage 2/3), Osteoporosis, Progressive Systemic Sclerosis, Rheumatoid Arthritis, Scoliosis of the Thoracic Spine, Spondylitis, Ankylosing, Systemic Lupus Erythematosus, Anomaly: Musculoskeletal System, Injury: Other and Ill-Defined Musculoskeletal Sites, Neoplasm, Benign: Musculoskeletal Syst. or Connective Tissue, Other Arthropathies, Bone and Joint Disorders, Other Disorders of Connective Tissue, Other Spinal and Back Disorders, Myasthenia Gravis, Complications of Surgical and Medical Care (stage 1), Injury, Open Wound, or Blunt Trauma: Abdomen or Trunk (stage 2/3), Injury: Other (stage 3)		Beginning in 2010, the following ICD-9-CM codes were in the record: 710-739	
Neurologic Diseases	Down's Syndrome, Herpes zoster, Poliomyelitis, Post-Polio Syndrome, Syphilis: Acquired, Tetanus (stage 1), Toxoplasmosis: Acquired (stage 3), Amyotrophic Lateral Sclerosis, Cerebral Palsy, Cerebrovascular Disease, Disease of Nervous System Secondary to Implants or Grafts, Epilepsy, Guillain-Barre Syndrome (stage 2), Headache (stage 2), Huntington's Chorea, Injury: Craniocerebral,	Anticholinesterase agents anticonvulsivant barbiturates and congeners alprostadil ergot alkaloids 5HT1 agonists dopamine	2005-2009: Visits prescribed due to the presence of Dementia and Alzheimer's syndrome, Parkinson's and

Predicting Risk Using a Population Based Longitudinal Database

Louis et al

STROBE Statement—checklist of items that should be included in reports of observational studies

	Item No	Recommendation	
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	See abstract section: Design.
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	The outcome measures used and what was found are summarized in the sections of the abstract: Main outcome measures and Results
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	See the Introduction section pages 4 and 5
Objectives	3	State specific objectives, including any prespecified hypotheses	Our objectives are described in the last two paragraphs of the Introduction
Methods			
Study design	4	Present key elements of study design early in the paper	See last paragraph of the Introduction and the Methods section
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	See <u>Study Data and Study Population</u> at beginning of Methods section
Participants	6	(a) <i>Cohort study</i> —Give the eligibility criteria, and the sources and methods of selection of participants. Describe methods of follow-up	Our study includes 100% of the adult population See <u>Study Data and Study Population</u> at beginning of Methods section
		(b) <i>Cohort study</i> —Give the eligibility criteria, and the sources and methods of case ascertainment and control selection. Give the rationale for the choice of cases and controls <i>Cross-sectional study</i> —Give the eligibility criteria, and the sources and methods of selection of participants	
		(b) <i>Cohort study</i> —For matched studies, give matching criteria and number of exposed and unexposed	
		<i>Case-control study</i> —For matched studies, give matching criteria and the number of controls per case	
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	See the Dependent variable and Independent variable sections in the Methods section
Data sources/ measurement	8*	For each variable of interest, give sources of data	See the Dependent variable

		and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	and Independent variable sections in the Methods section. In addition we have included an Appendix with detailed mapping to independent variable.
Bias	9	Describe any efforts to address potential sources of bias	See Evaluation of the Models (page 10) in the Methods section
Study size	10	Explain how the study size was arrived at	Our study includes 100% of the adult population
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	See the Dependent variable and Independent variable sections in the Methods section. In addition we have included an Appendix with detailed mapping to independent variable.
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	See the Modelling section and Evaluation of the Models section (pages 9 and 10) of the Methods
		(b) Describe any methods used to examine subgroups and interactions	See the Modelling section (pages 9 and 10) of the Methods
		(c) Explain how missing data were addressed	
		(d) <i>Cohort study</i> —If applicable, explain how loss to follow-up was addressed <i>Case-control study</i> —If applicable, explain how matching of cases and controls was addressed <i>Cross-sectional study</i> —If applicable, describe analytical methods taking account of sampling strategy	Our study includes 100% of the adult population
		(e) Describe any sensitivity analyses	See Evaluation of the Models last paragraph of Methods.
Results			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	See Page 11 Results section
		(b) Give reasons for non-participation at each stage	N/A
		(c) Consider use of a flow diagram	
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	See Table 1 and Results section (page 11-14)
		(b) Indicate number of participants with missing data for each variable of interest	

		(c) <i>Cohort study</i> —Summarise follow-up time (eg, average and total amount)	N/A
Outcome data	15*	<i>Cohort study</i> —Report numbers of outcome events or summary measures over time	
		<i>Case-control study</i> —Report numbers in each exposure category, or summary measures of exposure	
		<i>Cross-sectional study</i> —Report numbers of outcome events or summary measures	See Table 2 and figure and pages 14 and 15 of Results section
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	See pages 13
		(b) Report category boundaries when continuous variables were categorized	
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	See Table 2 and page 13 and 14.
Discussion			
Key results	18	Summarise key results with reference to study objectives	See Discussion section page 16
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	See Discussion section pages 17 and 18
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	See Discussion section page 18
Generalisability	21	Discuss the generalisability (external validity) of the study results	See Discussion section pages 18 and 19
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	The study was funded by the Emilia-Romagna, region of Italy. See page 3.

*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at <http://www.plosmedicine.org/>, Annals of Internal Medicine at <http://www.annals.org/>, and Epidemiology at <http://www.epidem.com/>). Information on the STROBE Initiative is available at www.strobe-statement.org.
