Comparison among four DNA barcodes. We compared the divergence of ITS2, *psbA-trnH*, *rbcL*, and *matK* regions. For each of the ten species, one to five samples were selected for a supplementary test (Table S4). The results indicated the following:

- (1) PCR amplification is highly successful for the ITS2 and *psbA-trnH* regions, whereas the *rbcL* and *matK* regions were not amplified in approximately one-third and one-fourth of the samples, respectively.
- (2) All the PCR products of the ITS2, *psbA-trnH*, and *rbcL* regions could be bi-directional sequenced and assembled successfully, whereas only the reverse sequencing results could be obtained for the *matK* region because of the poly T region (with approximately 11 thymines).
- (3) All the ITS2, *psbA-trnH*, *rbcL*, and *matK* sequences obtained in the experiment were aligned (Figure S1, S3-S5). Given that five species had no variability in the *rbcL* region (Figure S3) and the *matK* sequences of some samples could not be obtained in the experiment, these two markers (*rbcL* and *matK*) were deemed unsuitable for the identification of the ten *Rhodiola* species in this study. The *psbA-trnH* region could identify these species by BLAST1 analysis. Furthermore, ITS2 showed enough interspecies divergence to differentiate these species (main text page 5, line 25-28). The results demonstrated that the ITS2 barcode was able to accurately and swiftly distinguish the ten species.
- (4) These results confirmed that the ITS2 and *psbA-trnH* regions were acceptably capable of species identification. These conclusions are consistent with those in our previous study²⁵. Given that the use of one marker could solve the identification problem and minimize the cost in the experiment, we finally chose ITS2 as the DNA barcode in this study.

Table S1 List of specimens and authentic samples from the 10 *Rhodiola* species
