

1 **SUPPLEMENTAL MATERIAL**

2

3 **MOVIE S1:** Journey to the center of a honey-comb-like biofilm. Channels potentially acting  
4 as feeders of the biofilm were visualized. Propidium iodide staining showed the presence of  
5 red pockets of materials formed by a mixture of dead cells and released eDNA. The movie  
6 was realised from a 3D reconstruction of CLSM acquisitions using IMARIS software.

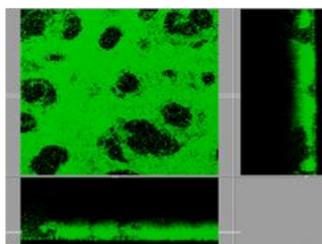

7

8

9 **MOVIE S2:** Both motile and sessile bacteria are visualized in a 48h honey-comb-like  
10 biofilm. Swimming bacteria are preferentially located in the hollow voids. Real time  
11 recording was achieved by XY images acquired every 1.6 s for 90 s using CLSM acquisitions.  
12 Real time is indicated in the lower left-hand corner.

13

14

15 **MOVIE S3:** Planktonic 10403S-GFP bacteria progressively adhere to the surface to form  
16 microcolonies and a network of sessile bacteria after 48h. Time-lapse confocal imaging was  
17 achieved by acquisition every 30 min for 48h.

18 **TABLE S1:** Characteristics of *Listeria monocytogenes* isolates used in this study (ListRA  
 19 collection).

21

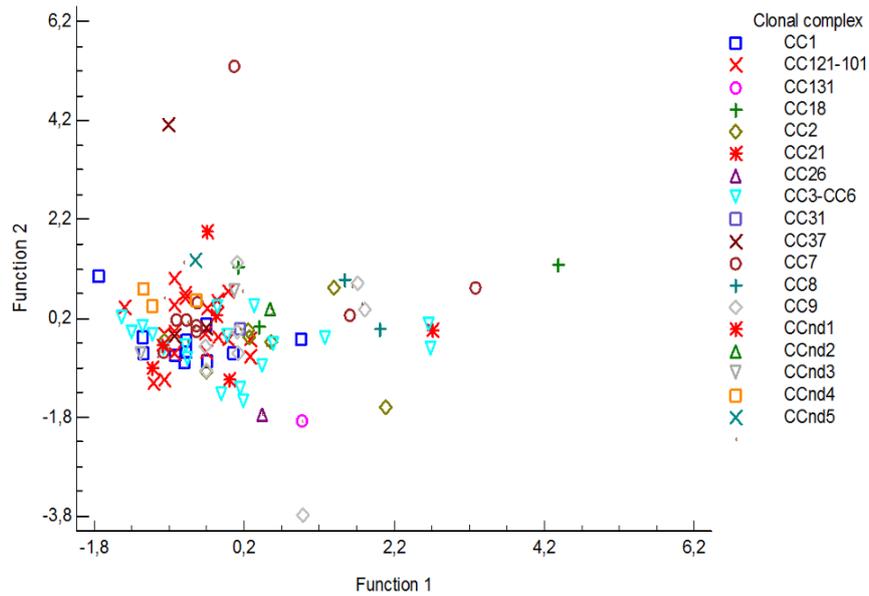

22 INRA : Institut National de la Recherche Agronomique ; CIP: Collection de l'Institut  
 23 Pasteur ; ISHA : Institut Scientifique d'Hygiène et d'Analyse.

24 <sup>1</sup> Genotyping was achieved by sequencing two housekeeping genes: *cat* and *dapE* (see  
 25 Material and Methods section)

26 <sup>2</sup> Swimming tests were performed using 5 µL of each strain subculture inoculated in the  
 27 center of swimming agar (TSB+0.25% agar). After incubation of the plates 24 h at 25°C,  
 28 swimming diameter was measured and motile (+) and non-motile strains (-) were identified.  
 29 Experiments were performed three times independently.

30 <sup>3</sup> Mean thickness (µm), roughness and biovolume (µm<sup>3</sup>) were calculated from the CLSM  
 31 images (means of four acquisitions) using PHLIP, a MATLAB-based image analysis toolbox.

32

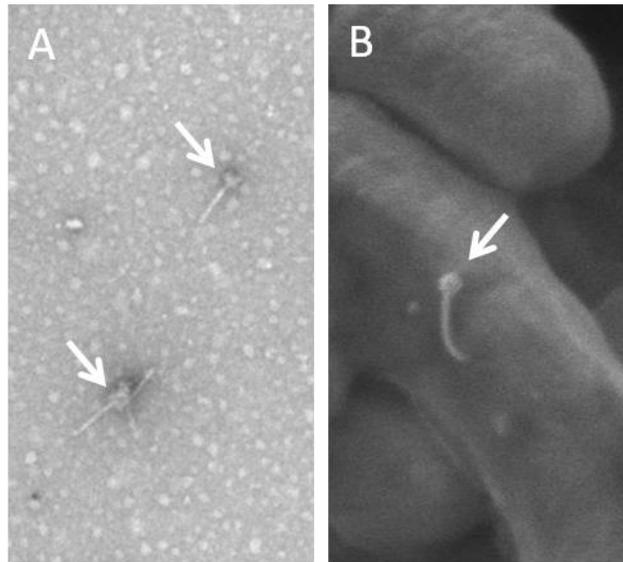

34

35 **FIG S1:** Strains classification in the clonal complexes using the biofilm structural parameters  
 36 (thickness, roughness and biovolume). Two discriminating functions were developed using a  
 37 discriminant analysis. Discriminant function 1 was statistically significant with  $P$ -value  $<0.05$   
 38 at the 95% confidence level and improved probability to correctly classify strains in the clonal  
 39 complexes from 0.06 to 0.24.

40

41  
42

43  
44

45 **FIG S2:** Phages observed in biofilm supernatant after negative staining with Transmission  
46 Electron Microscopy (Zeiss EM902 EELS) (A) and on cells in biofilms with Scanning  
47 Electron Microscopy (B) (white arrows). Concomitant observations of phages and eDNA in  
48 the biofilms hypothesize the occurrence of localized cell death caused by the expression of  
49 prophages.
