Supplementary Figure S1. Confidence score indices sorted by discrimination performance.

The results of confidence score index (CSI) were sorted based on discrimination performance. This analysis showed that the CSI in the 0.020 s and 0.027 s conditions were not statistically different between correct and error trials (paired t-test, 0.020 s: $t_{(90)} = 1.577$, $p \approx 1.000$, 0.027 s: $t_{(90)} = 1.549$, $p \approx 1.000$ with BC), but were significantly different in other conditions (paired t-test, 0.033 s: $t_{(90)} = 6.012$, $p < 0.0001$, 0.040 s: $t_{(90)} = 8.981$, $p < 0.0001$, 0.047 s: $t_{(90)} = 8.564$, $p < 0.0001$ with BC).
