## **Clinical assessment**

### **Discovery Cohort**

The discovery cohort consisted of 607 adulthood ADHD cases (61% combined, 35% inattentive, 3.5% hyperactive-impulsive and 0.5% with undefined subtype) and 584 healthy controls from Spain. All patients were adults of Caucasian origin, recruited and evaluated at the Hospital Universitari Vall d'Hebron located in Barcelona (Spain), and met Diagnostic and Statistical Manual for Mental Disorders-IV (DSM-IV) criteria for ADHD. The diagnosis of ADHD was evaluated with the Structured Clinical Interview for DSM-IV Axis I and II Disorders (SCID-I and SCID-II) and the Conner's Adult ADHD Diagnostic Interview for DSM-IV (CAADID Parts I and II). Severity of ADHD symptoms was evaluated with the long version of the Conners' ADHD Rating Scale (self-report form CAARS-S:L and observer form CAARS-O:L), the ADHD Rating Scale (ADHD-RS), the ADHD Screening Checklist and the Wender Utah Rating Scale (WURS) for retrospective symptomatology. The level of impairment was measured with the Clinical Global Impression (CGI), included in the CAADID Part II, and the Sheehan Disability Inventory (SDI). For the evaluation of psychiatric symptoms, patients were filled in the Beck Depression Inventory (BDI), the State Trait Anxiety Inventory (STAI) and the Millon Clinical Multiaxial Inventory (MCMI-II). Full-Scale IQ was estimated with the Vocabulary and Block Design subtests of the WAIS-III. Patients also completed the digit span, arithmetic, Letter-Number Sequencing and Symbol Search subtests of the WAISIII, the Conners' Continuous Performance Test (CPT), the California Verbal Learning Test (CVLT), the Logical Memory I-II and Visual Memory I-II of the WMS-R and the trail-making test (Parts A and B). The control sample consisted of two subsets: (i) 584 unrelated blood donors frequency-matched for gender with the ADHD group in which DSM-IV life-time ADHD symptoms were excluded under the following criteria: (1) Not having previously been diagnosed with ADHD and (2) answering negatively to the life-time presence of the following DSM-IV ADHD symptoms: (a) often has trouble keeping attention on tasks, (b) often loses things

needed for tasks, (c) often fidgets with hands or feet or squirms in seat and (d) often gets up from seat when remaining in seat is expected and (ii) 149 control subjects from the Infancia y Medio Ambiente (INMA; (<http://www.proyectoinma.org>) (Guxens et al. 2012). All of them were assessed for ADHD symptoms using the DSM-IV test at the age of 4 years and controls were defined as fulfilling less or equal to four DSM-IV symptoms. All of them were born from white European parents and did not show any population substructure in the principal components analysis (PCA) using genome-wide genotypic data. The average age at assessment was 31.0 years (SD=11.7) for patients and 33.6 (SD=21.3) for control subjects.

### **Replication Cohorts**

In total, 2,104 adult ADHD patients and 1,901 controls of Caucasian origin from three European countries (Germany, The Netherlands and Norway) were recruited at three sites of The International Multicentre Persistent ADHD CollaboraTion (IMpACT; Table S1). Consensus eligibility criteria for the current study across all sites were a diagnosis of ADHD according to the diagnostic criteria of DSM-IV, onset before the age of 7 years via retrospective diagnosis (which was confirmed by a family member, wherever possible), lifelong persistence and current diagnosis. Patients were extensively examined by psychiatrists experienced in adult ADHD using open and semi-structured interviews. Other psychiatric disorders were evaluated with the Structured Clinical Interview of DSM-IV for axis-I and axis-II disorders (SCID-I, SCID-II) or semi-structured interviews. Most controls (except for the Norwegian samples and part of the German samples) were screened for the presence of ADHD and those scoring high on symptoms of the disorder were excluded. Each of these datasets has been described elsewhere (Franke et al. 2010 ; Landaas et al. 2010) For a more detailed description of the different diagnostic instruments, see Sanchez-Mora et al. et al. et al. (Sánchez-Mora et al. 2010).

The study was approved by the ethics committee of each institution and informed consent was obtained from all participants in accordance with the Helsinki Declaration.

## **Brain imaging studies**

Structural brain changes were tested by Voxel Based Morphometry (VBM) using structural T1 brain scans acquired at 1.5 Tesla and 3 Tesla scanners (Siemens, Erlangen, Germany). The scanning protocols included small variations to a standard T1-weighted 3D MPRAGE sequence (TR 2300 ms, TI 1100 ms, TE 3.03 ms, 192 sagittal slices, field of view 256 mm); however, these variations have been shown to not affect the reliability of the imaging results (Jovicich et al. 2010). Raw DICOM images were converted to NIFTI format using the conversion tool implemented in SPM5 ([www.fil.ion.ucl.ac.uk/spm/software/spm5/](http://www.fil.ion.ucl.ac.uk/spm/software/spm5/)). As a next step, the VBM 5.1 toolbox version 1.19 in SPM using priors (default settings) was used to normalize, perform a bias-correction, and segment the images into grey and white matter. This method includes an optimized VBM protocol as well as a model to increase the signal to noise ratio (Hidden Markov Random Fields) (Cuadra et al. 2005). Total Brain Volume (TBV) was defined as the sum of resulting tissue probabilities of grey and white matter volumes. The VBM analysis was performed in SPM5 and included the Diffeomorphic Anatomical registration using Exponentiated Lie Algebra (DARTEL) toolbox. Subsequently, Jacobian-scaled images were calculated and an affine transformation was used to transform to Montreal Neurological Institute (MNI) space, after which all data were smoothed with an 8 mm FWHM Gaussian smoothing kernel. Images with poor quality, artifacts or more than 1.5 times the interquartile range from the median were excluded.
