

SUPPLEMENTARY MATERIAL

FIGURE S1

A Mapping data from the human deafness family. Genomewide SNP mapping in the deafness family revealed candidate regions with homozygosity by descent on chromosomes 6, 7 and 11. *AHI1* is localized about 5 Mb centromeric of the chromosome 6 candidate locus. **B** Western blot of fibroblast lysates that were probed with polyclonal rabbit IgG antibodies against *AHI1*. *AHI1* isoforms (red arrows) are expressed in fibroblasts from a homozygous mutation carrier, II:4, and in fibroblasts from a healthy control proband (ctrl.). PA5-30901 (left half of the panel) recognizes a region between *AHI1* residues 383-596, PA31846 (right half of the panel) recognizes a region between residues 1-231. As internal control, the monoclonal mouse anti β -actin (Sigma, Cat.-Nr. A2228) antibody recognizing human β -actin was used.

FIGURE S2

A Detail of the family 1 pedigree showing SNP genotyping data of the siblings from genome-wide linkage analysis. Because *AHI1* locates within an HBD region (between SNPs rs2327578 and rs724875) shared by the three deaf individuals (II:3, II:5, II:6) and the healthy person II:4, the p.Arg1066* mutation can be considered truly homozygous in all these individuals. **B** Overview of the family including the parents, showing heterozygous haplotypes in the parents.

FIGURE S3

A Evolutionary conservation of the p.Ser671 residue. **B** WD40 repeats of *AHI1* as predicted by ScanProsite. Note that ScanProsite predicts only four of the seven WD40 repeats. **C** ScanProsite predicts loss of the WD40 repeat affected by the p.Ser671Leu mutation.

TABLE S1

Secondary structure prediction of AHI1 by the WDSP algorithm. Each WD40 repeat starts from Loop_da, followed by Strand a, Loop_ab, Strand_b, Loop_bc, Strand_c, Loop_cd, and Strand d. Thus, KHLFSL is the Strand-d of WD7. The red residues are involved in hydrogen bond networks.
