

## Genetic architecture of murine skin inflammation and tumor susceptibility (Supplementary data)

**Supplementary Figure 1**

**Distribution of significant trans-eQTL in FVBX tail epidermis.** This figure plots the distribution of all eQTL measured in skin ( $\leq 5\%$  FDR). Genomic location of SNPs across all chromosomes is plotted on the horizontal axis; location of probes is plotted on the vertical axis. No eQTL were calculated on the X or Y chromosomes. Solid vertical lines separate chromosomes. The dark line along the diagonal are putative *cis*-eQTL. Arrows indicate significant hot-spots (chi-squared test, Bonferroni correction for 223 tests). Total trans-eQTL count = 1034. (see Supplementary Tables 1,2 for specific chromosome and SNP breakdowns).

**Supplementary Figure 2**

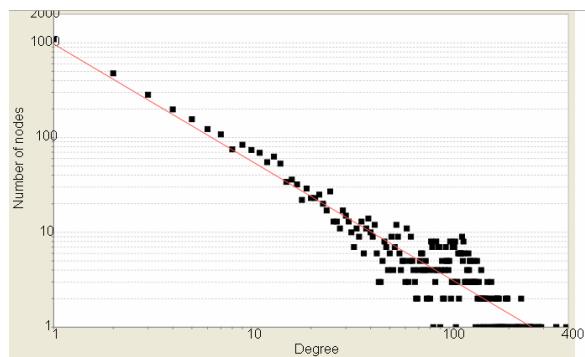

Gene expression in parental mice shows genetic influence on functionally related genes

The Y-axis is the log-transformed mean of four biological replicate gene expression values measured in FVB/N, SPRET/Ei, and FVB x SPRET F1 animals with Affymetrix arrays. All genes are significantly different between strains (FDR  $q$ -value = 0 for all genes).

(A) Gene expression of representative hair follicle genes. Structural genes are shown in black; transcription factors *Hoxc13*, *Dlx3*, and *Msx2* are shown in blue.

(B) Gene expression of melanin biosynthesis genes.

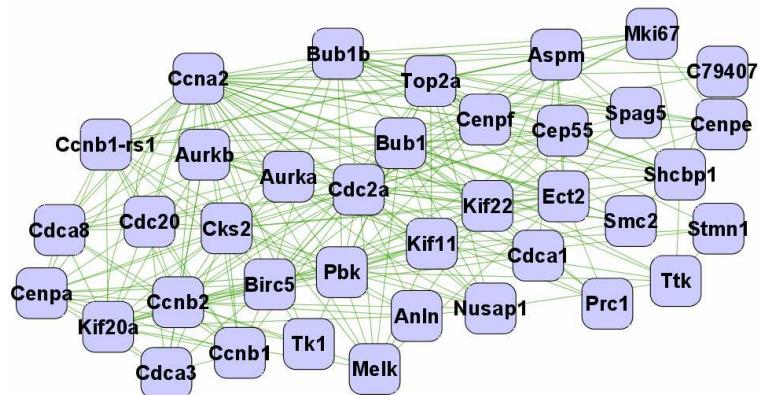

### Supplementary Figure 3

#### Degree Distribution of FVBBX correlation network.

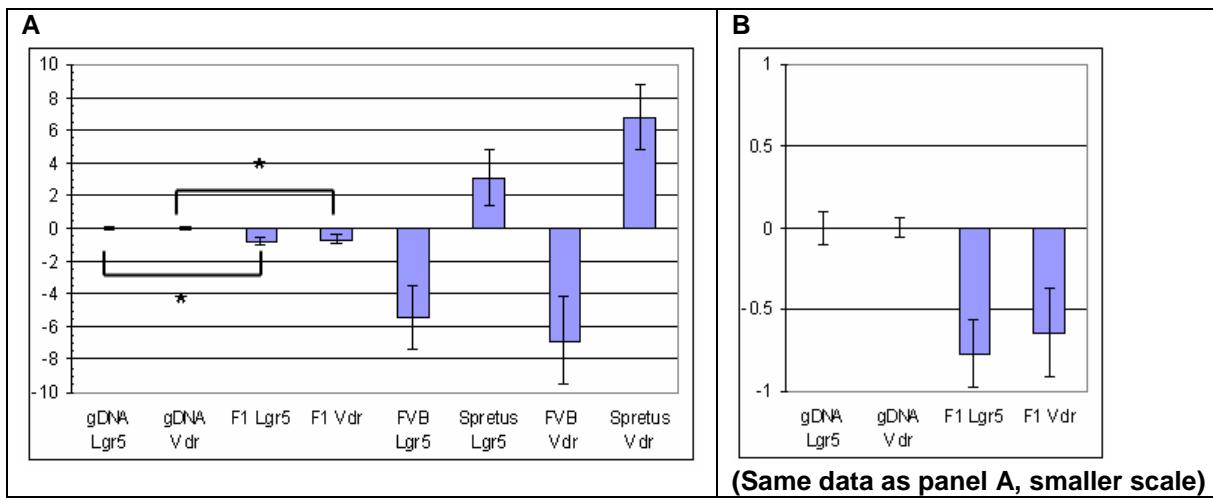

Structural characteristics of the FVBBX relevance network were calculated using the NetworkAnalyzer<sup>31</sup> plug-in for Cytoscape. The correlation coefficient cut-off for the relevance network was 0.8. The network contains 3933 nodes and 40,335 edges. The mean number of neighbors is 19.3 and the mean clustering coefficient is 0.35. The network is plausibly scale-free, as a linear least-squares fit of the log degree to log number of nodes had an r-squared value of 0.88 for a power law of the form  $y=969.25x^{-1.235}$ .

### Supplementary Figure 4

**Cell Cycle gene correlation network in FVBBX.** Edges indicate correlation  $r^2 \geq 0.64$ . This clique was automatically identified from the FVBBX tail epidermal gene expression.

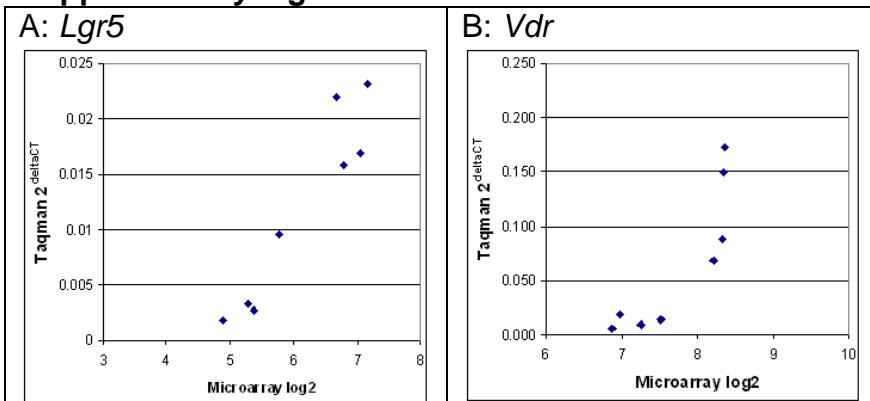

## Supplementary Figure 5

### Taqman validation of allele-specific expression of *Lgr5* and *Vdr* in parental and F1 animals.

Cis-regulation of *Vdr* and *Lgr5* was verified by a cis-trans test. We performed allele-specific Taqman of SPRET/Ei ( $n = 4$ ), FVB/N ( $n = 4$ ), and F1 ( $n = 3$ ) RNA. Allele-specific Taqman probes were designed by sequencing *Lgr5* and *Vdr* in SPRET/Ei and FVB/N. The first two columns show  $\Delta\Delta Ct$  for the genomic DNA used as a control to adjust for unequal efficiency of the FAM and VIC probes. The next two columns show  $\Delta\Delta Ct$  values for *Lgr5* and *Vdr* probes in F1 (also presented at right, smaller scale). The last four columns show  $\Delta\Delta Ct$  values for *Lgr5* and *Vdr* probes in FVB/N and SPRET/Ei. Although the measured effect is modest, the difference from genomic DNA is significant ( $p < 0.05$ , both genes).

## Supplementary Figure 6

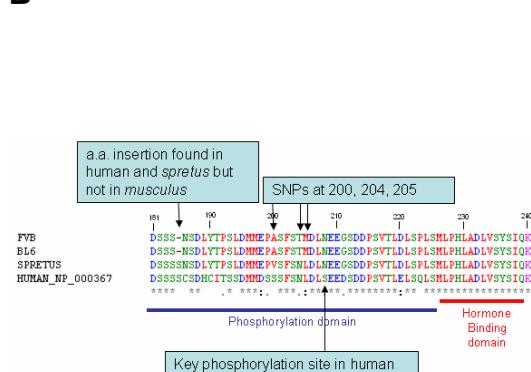

**Taqman validation of microarray expression measurements of *Lgr5* and *Vdr*.** *Lgr5* and *Vdr* expression in parental FVB/N and SPRET/Ei strains as measured by Taqman was compared expression measured by Affymetrix microarray. *Lgr5* expression as measured by Taqman is highly correlated with expression measured by the microarray (correlation r-squared value 0.81, p-value 0.005). Expression of *Vdr* as measured by Taqman is highly correlated with expression measured by Affymetrix microarray (correlation r-squared 0.85, p-value 0.002).

**Aligned protein sequences of FVB/N, C57/B6, SPRET/Ei, and human *Vdr*.** We sequenced the coding exons of the *Vdr* in FVB/N and SPRET/Ei mice and aligned the imputed protein sequences against C57/BL6 and the human NP\_000367 *Vdr* sequence (**A**). For the first 180 human amino acids (a.a.) there are no non-synonymous coding changes between mouse species in *Vdr*. There are

several loci that differ between human and mouse, and four inserted human a.a. not found in mouse. There are three protein-coding changes between FVB/N and SPRET/Ei in the second *Vdr* phosphorylation domain and an a.a. inserted in human and SPRET/Ei but not *Mus musculus* (**B**). S208 is known to be a key phosphorylation site in humans. There is also a SNP resulting in a protein change between Spretus and FVB in the hormone-binding domain at human a.a. 281.

### Supplementary Figure 8

**Distinct *Vdr* correlation networks for mice homozygous and heterozygous at Chr15, 101 Mb.**  
Genes correlated with *Vdr* in mice homozygous for FVB/N at Chr15:101 Mb (A) or heterozygous FVB/SPRET at that locus (B). Green lines indicate direct correlation; red lines indicate inverse correlation. R-squared values are 0.49 or higher ( $r \geq 0.7$  or  $r \leq -0.7$ ).

It has been shown that *Vdr* ablation sensitizes skin to chemical and UV models of tumorigenesis<sup>32,33</sup>. Our results show that FVB BX mice with a spretus allele at Chr 15:101 Mb have lower levels of *Vdr*, which is associated with higher tumor susceptibility. We performed differential correlation analyses of *Vdr* to identify the individual co-expression networks for mice heterozygous at Chr 15:101 Mb ( $n=39$ ) and mice homozygous at that allele ( $n = 32$ ). There is not a significantly non-random sex distribution in these groups (chi-squared test). Using a r-squared cut-off of 0.49, *Vdr* is correlated with genes that affect *Wnt* signaling and tumor susceptibility in homozygous mice but not in heterozygous mice (Figure 2A, 2B). The strongest correlation in the homozygous *Vdr* network is between *Vdr* and the tumor suppressor *Cdkn1a* (*p21*). It is known that *Vdr* binds *p21* directly and this binding increases *p21* expression<sup>34</sup>. *TGFB* inhibitory gene *Smad7*, which induces beta-catenin degradation<sup>35</sup>, is one of several *Wnt* modifiers in the homozygous correlation network. *Vdr* is transactivated by *Smad3*<sup>36</sup>, and *Smad7* disrupts the binding of *Vdr* with *Smad3*<sup>37</sup>. The homozygous *Vdr*-correlated transcription factors *Foxo1* and *Foxo3a* compete with TCF for the opportunity to bind beta-catenin, which activates *Foxo* signaling. This activation inhibits cell cycle progression<sup>38 39</sup>. Connections between *Vdr* and *Wnt* signaling have been identified by Cianferotti and co-workers who recently showed that the cooperative effects of *Wnt* signaling genes *Ctnnb1* and *Lef1* are abolished in keratinocytes derived from *Vdr* knockout mice<sup>40</sup>. Other genes in this signature (*Igf1r*, *Ddit4*, *Bcl6*, *Tns4*, *Ets2*, *Hdgfrp3*, *Gadd45g*, and *Epha2*) have been linked directly to tumor susceptibility and proliferation.

Importantly, genes in the *Vdr*-homozygous network are absent in *Vdr*-heterozygous mice. The correlation network in *Vdr*-heterozygous mice is recapitulated at lower stringency in *Vdr*-homozygous mice but not vice-versa (data not shown), suggesting genetic differences may have far-reaching physiological consequences. We sequenced the coding exons of *Vdr* in SPRET/Ei and FVB/N and identified four polymorphisms between these species that result in amino acid changes (Supplementary Figure 7).

The same analysis was then performed for *Lgr5*, identifying the individual co-expression networks for mice heterozygous at Chr 10:118 Mb ( $n=31$ ) and mice homozygous at that allele ( $n = 42$ ). There is not a significantly non-random sex distribution in these groups (chi-squared test). Using a r-squared cut-off of 0.49, *Lgr5* is correlated with very similar networks of hair-follicle and epidermal genes in both the *Lgr5*-homozygous and *Lgr5*-heterozygous groups. The principle difference

between the networks is that *Lgr5* is more highly correlated with hair follicle keratins in the *Lgr5*- homozygous group. One possible explanation for this result is the overall much lower expression of hair follicle-related genes in SPRET/Ei tail RNA; hair follicle signaling may be attenuated in these animals, and animals receiving a SPRET/Ei allele have commensurately lower overall levels of hair follicle expression. This is compatible with the fact that these keratins have eQTL at the Chr 10:118 Mb. locus.

### Supplementary Table 1

#### SNPs that are significantly frequent locations for *trans*-eQTL peaks in mouse skin.

P-values from chi-squared test. This lists all SNPs with significant p-values after 0.05 Bonferroni corrected of an alpha level 0.05 for 223 tests. Total *trans*-eQTL count was 1034.

SNP Location	<i>trans</i> -eQTL count	P-value
Chr. 2, 85 Mb.	63	2.0 * 10 <sup>-12</sup>
Chr. 15, 73 Mb.	50	1.3 * 10 <sup>-9</sup>
Chr. 1, 29 Mb.	47	5.7 * 10 <sup>-9</sup>
Chr. 1, 16 Mb.	43	4.1 * 10 <sup>-8</sup>
Chr. 9, 52 Mb.	41	1.1 * 10 <sup>-7</sup>
Chr. 1, 8 Mb.	29	3.9 * 10 <sup>-5</sup>
Chr. 7, 79 Mb.	27	1.0 * 10 <sup>-4</sup>

### Supplementary Table 2

#### Details of the eQTL distribution

Highlighted p-values are chromosomes that have significantly more *trans*-eQTL than expected by chance after Bonferroni correction

### Supplementary Table 5

#### Non-synonymous changes in Lgr5 sequence between SPRET/Ei and FVB/N

We sequenced the coding exons of *Lgr5* in SPRET/Ei and FVB/N and identified four polymorphisms between these species that result in amino acid changes:

Lgr5 Amino Acid Location	FVB/N	Spretus	Human	Domain
90	C	R	R	Leucine-rich repeat 2
774	A	T	T	Trans-membrane 6
813	S	A	A	Trans-membrane 7
886	A	S	P	C-terminal tail

**Supplementary Table 6**

**Supplementary Table 8**  
**Genes differentially expressed between low-susceptibility mice (zero papillomas at 20 weeks) and high-susceptibility mice (eight or more papillomas at 20 weeks).** Genes listed first with gene symbol on a white background are higher in mice with eight or more papillomas; genes listed later on a green background are lower in that group (i.e. have inverse directionality with papilloma number).
